A Corporate Dedication to Quality and Reliability

National Semiconductor is an industry leader in the manufacture of high quality, high reliability integrated circuits. We have been the leading proponent of driving down IC defects and extending product lifetimes. From raw material through product design, manufacturing and shipping, our quality and reliability is second to none.

We are proud of our success . . . it sets a standard for others to achieve. Yet, our quest for perfection is ongoing so that you, our customer, can continue to rely on National Semiconductor Corporation to produce high quality products for your design systems.

Charles E. Sporck
President, Chief Executive Officer
National Semiconductor Corporation

Charles E. Sporck

National Semiconductor Corporation

Wir fühlen uns zu Qualität und Zuverlässigkeit verpflichtet

National Semiconductor Corporation ist führend bei der Herstellung von integrierten Schaltungen hoher Qualität und hoher Zuverlässigkeit. National Semiconductor war schon immer Vorreiter, wenn es galt, die Zahl von IC Ausfällen zu verringern und die Lebensdauern von Produkten zu verbessern. Vom Rohmaterial über Entwurf und Herstellung bis zur Auslieferung, die Qualität und die Zuverlässigkeit der Produkte von National Semiconductor sind unübertroffen.

Wir sind stolz auf unseren Erfolg, der Standards setzt, die für andere erstrebenswert sind. Auch ihre Ansprüche steigen ständig. Sie als unser Kunde können sich auch weiterhin auf National Semiconductor verlassen.

La Qualité et La Fiabilité:

Une Vocation Commune Chez National Semiconductor Corporation

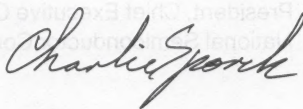

National Semiconductor Corporation est un des leaders industriels qui fabrique des circuits intégrés d'une très grande qualité et d'une fiabilité exceptionnelle. National a été le premier à vouloir faire chuter le nombre de circuits intégrés défectueux et à augmenter la durée de vie des produits. Depuis les matières premières, en passant par la conception du produit sa fabrication et son expédition, partout la qualité et la fiabilité chez National sont sans équivalents.

Nous sommes fiers de notre succès et le standard ainsi défini devrait devenir l'objectif à atteindre par les autres sociétés. Et nous continuons à vouloir faire progresser notre recherche de la perfection; il en résulte que vous, qui êtes notre client, pouvez toujours faire confiance à National Semiconductor Corporation, en produisant des systèmes d'une très grande qualité standard.

Un Impegno Societario di Qualità e Affidabilità

National Semiconductor Corporation è un'industria al vertice nella costruzione di circuiti integrati di alta qualità ed affidabilità. National è stata il principale promotore per l'abbattimento della difettosità dei circuiti integrati e per l'allungamento della vita dei prodotti. Dal materiale grezzo attraverso tutte le fasi di progettazione, costruzione e spedizione, la qualità e affidabilità National non è seconda a nessuno.

Noi siamo orgogliosi del nostro successo che fissa per gli altri un traguardo da raggiungere. Il nostro desiderio di perfezione è d'altra parte illimitato e pertanto tu, nostro cliente, puoi continuare ad affidarti a National Semiconductor Corporation per la produzione dei tuoi sistemi con elevati livelli di qualità.

LIFE SUPPORT POLICY

NATIONAL'S PRODUCTS ARE NOT AUTHORIZED FOR USE AS CRITICAL COMPONENTS IN LIFE SUPPORT DEVICES OR SYSTEMS WITHOUT THE EXPRESS WRITTEN APPROVAL OF THE PRESIDENT OF NATIONAL SEMICONDUCTOR CORPORATION. As used herein:

1. Life support devices or systems are devices or systems which, (a) are intended for surgical implant into the body, or (b) support or sustain life, and whose failure to perform, when properly used in accordance with instructions for use provided in the labeling, can be reasonably expected to result in a significant injury to the user.
2. A critical component is any component of a life support device or system whose failure to perform can be reasonably expected to cause the failure of the life support device or system, or to affect its safety or effectiveness.

National Semiconductor Corporation 2900 Semiconductor Drive, P.O. Box 58090, Santa Clara, California 95052-8090 (408) 721-5000 TWX (910) 339-9240

National does not assume any responsibility for use of any circuitry described, no circuit patent licenses are implied, and National reserves the right, at any time without notice, to change said circuitry or specifications.

Linear Products Introduction

National Semiconductor Corporation first established itself as the Linear Leader in 1967 with the introduction of the FIRST MONOLITHIC VOLTAGE REGULATOR . . . LM100. In the 20 years since, many of our products were firsts in performance and function. Today, this catalog spans the traditional areas of Op Amps, Voltage Regulators, Voltage References and Temperature Sensors, to Data Acquisition, Communication, Automotive, and Power Plus Control. National Semiconductor intends to remain a leader in the traditional product areas while forging ahead into VLSI solutions for analog problems and analog systems.

You can rely on National LINEAR to develop the most comprehensive product offering for use in the commercial, computer, automotive, telecommunication, industrial or military business segments. More than 1,000 basic LINEAR products (5400 options) allow design engineers to find the optimum Linear IC solution from National Semiconductor.

The Linear product line is presented in 3 Databooks. All sections are referenced and cross-indexed to provide quick and easy access. The technical information and basic product specifications are presented in data sheet format, including maximum ratings, electrical characteristics, performance curves and package information.

Additional application information is available as specific application notes or completely compiled in the LINEAR APPLICATIONS HANDBOOK. A product cross reference to the specific application note has been provided. This handbook and the 3-volume set of Linear Data Books represent a complete base of information to the National LINEAR product line.

Product Status Definitions

Definition of Terms

Data Sheet Identification	Product Status	Definition
Advanced Information	Formative or In Design	This data sheet contains the design specifications for product development. Specifications may change in any manner without notice.
Preliminary	First Production	This data sheet contains preliminary data and supplementary data will be published at a later date. National Semiconductor Corporation reserves the right to make changes at any time without notice in order to improve design and supply the best possible product.
No Identification Noted	Full Production	This data sheet contains final specifications. National Semiconductor Corporation reserves the right to make changes at any time without notice in order to improve design and supply the best possible product.

National Semiconductor Corporation reserves the right to make changes without further notice to any products herein to improve reliability, function or design. National does not assume any liability arising out of the application or use of any product or circuit described herein; neither does it convey any license under its patent rights, nor the rights of others.

CROSS REFERENCE BY PART NUMBER

A complete interchangeability list of Linear IC's offered by most Integrated Circuit Manufacturers are listed in this section and reference the nearest National Semiconductor Corp. direct replacement or recommended replacement with either an improved or functional replacement. The following notations are appended to assist you in finding the best option.

- No reference note "DIRECT REPLACEMENT"
- Note (1) "IMPROVED REPLACEMENT" Pin-for-Pin replacement with "SUPERIOR" Electrical Specifications.
- Note (2) "FUNCTIONAL REPLACEMENT" Similar device. Consult datasheet to determine the suitability for specific application.
- Note (3) "SIMILAR DEVICE" with superior performance. Consult datasheet to determine suitability of the replacement for specific application.

Active Filters Definition of Terms

f_{CLK} : the switched capacitor filter external clock frequency.

f_o : center of frequency of the second order function complex pole pair. f_o is measured at the bandpass output of each $\frac{1}{2}$ MF10, and it is the frequency of the bandpass peak occurrence.

Q: quality factor of the 2nd order function complex pole pair. Q is also measured at the bandpass output of each $\frac{1}{2}$ MF10 and it is the ratio of f_o over the -3 dB bandwidth of the 2nd order bandpass filter. The value of Q is not measured at the lowpass or highpass outputs of the filter, but its value relates to the possible amplitude peaking at the above outputs.

H_{OBP} : the gain in (V/V) of the bandpass output at $f = f_o$.

H_{OLP} : the gain in (V/V) of the lowpass output of each $\frac{1}{2}$ MF10 at $f \rightarrow 0$ Hz.

H_{OHP} : the gain in (V/V) of the highpass output of each $\frac{1}{2}$ MF10 as $f \rightarrow f_{CLK}/2$.

Q_Z : the quality factor of the 2nd order function complex zero pair, if any. (Q_Z is a parameter used when an allpass output is sought and unlike Q it cannot be directly measured).

f_Z : the center frequency of the 2nd order function complex zero pair, if any. If f_Z is different from f_o , and if the Q_Z is quite high it can be observed as a notch frequency at the allpass output.

f_{notch} : the notch frequency observed at the notch output(s) of the MF10.

H_{ON1} : the notch output gain as $f \rightarrow 0$ Hz.

H_{ON2} : the notch output gain as $f \rightarrow f_{CLK}/2$.

Analog Switch Definition of Terms

R_{ON} : Resistance between the output and the input of an addressed channel.

I_S : Current at any switch input. This is leakage current when the switch is ON.

I_D : Current at any switch input going into the switch. This is leakage current when the switch is OFF.

C_S : Capacitance between any open terminal "S" and ground.

C_D : Capacitance between any open terminal "D" and ground.

$I_D - I_S$: Leakage current that flows from the closed switch into the body. This leakage is the difference between the current I_D going into the switch and the current I_S going out of the switch.

t_{RAN} : Delay time when switching from one address state to another.

t_{ON} : Delay time between the 50% points of an enable input and the switch ON condition.

t_{OFF} : Delay time between the 50% points of the enable input and the switch OFF condition.

Definition Of Terms A/D Converters

Conversion Time: The time required for a complete measurement by an analog-to-digital converter.

DC Common-Mode Error: This specification applies to ADCs with differential inputs. It is the change in the output code that occurs when the analog voltages on the two inputs are changed by an equal amount. It is expressed in LSBs.

Differential Nonlinearity: Ideally, any two adjacent digital codes correspond to measured analog voltages that are exactly one LSB apart. Differential non-linearity is a measure of the worst case deviation from the ideal 1 LSB step. For example, a DAC with a 1.5 LSB output change for a 1 LSB digital code change exhibits $\frac{1}{2}$ LSB differential non-linearity. Differential non-linearity may be expressed in fractional bits or as a percentage of full scale. A differential non-linearity greater than 1 LSB will lead to a non-monotonic transfer function in a DAC and missing codes in an ADC.

Gain Error (Full Scale Error): For an ADC, the difference (usually expressed in LSBs) between the input voltage that should ideally produce a full scale output code and the actual input voltage that produces that code. For DACs, it is the difference between the output voltage (or current) with full scale input code and the ideal voltage (or current) that should exist with a full scale input code.

Gain Temperature Coefficient (Full Scale Temperature Coefficient): Change in gain error divided by change in temperature. Usually expressed in parts per million per degree Celsius (ppm/ $^{\circ}$ C).

Integral Nonlinearity (Linearity Error): Worst case deviation from the line between the endpoints (zero and full scale). Can be expressed as a percentage of full scale or in fractions of an LSB.

LSB (Least-Significant Bit): In a binary coded system this is the bit that carries the smallest value or weight. Its value is the full scale voltage (or current) divided by 2^n , where n is the resolution of the converter.

Missing Codes: When an incremental increase or decrease in input voltage causes the converter to increment or decrement its numeric output by more than one LSB the converter is said to exhibit "missing codes". If there are missing codes, there is a numeric value on the output on the converter which cannot be reached by any input voltage value.

Monotonicity: A monotonic function has a slope whose sign does not change. A monotonic DAC has an output that changes in the same direction (or remains constant) for each increase in the input code. The converse is true for decreasing codes.

MSB (Most Significant Bit): In a binary coded system this is the bit that has the largest value or weight. Its value is one half of full scale.

Multiplying DAC: In a sense, every DAC is a multiplying DAC since the output voltage (or current) is equal to the reference voltage times a constant determined by the digital input code divided by 2^n (n is the number of bits of resolution). In a two quadrant multiplying DAC the reference voltage or the digital input code can change the output voltage polarity. If both the reference voltage and the digital code change the output voltage polarity four quadrant multiplication exists.

Offset Error (Zero Error): In a DAC, this is the output voltage that exists when the input digital code is set to give an ideal output of zero volts. In the case of an ADC, this is the difference between the ideal input voltage ($\frac{1}{2}$ LSB) and the actual input voltage that is needed to make the transition from zero to 1 LSB. All the digital codes in the transfer curve are offset by the same value. Many converters allow nulling of offset with an external potentiometer. Offset error is usually expressed in LSBs.

Power Supply Rejection (Power Supply Sensitivity): The sensitivity of a converter to changes in the dc power supply voltages.

Quantizing Error: The error inherent in all A/D conversions. Since even an "ideal" converter has finite resolution, any analog voltage that falls between two adjacent output codes will result in an output code that is inaccurate by up to $\frac{1}{2}$ LSB.

Ratiometric Operation: Many A/D applications require a stable and accurate reference voltage against which the input voltage is compared. This approach results in an **absolute conversion**. Some applications, however, use transducers or other signal sources whose output voltages are proportional to some external reference. In these **ratiometric** applications, the reference for the signal source should be connected to the reference input of the converter. Thus, any variations in the source reference voltage will also change the converter reference voltage and produce an accurate conversion.

Resolution: The smallest analog increment corresponding to a 1 LSB converter code change. For converters, resolution is normally expressed in bits, where the number of analog levels is equal to 2^n . As an example, a 12-bit converter divides the analog signal into $2^{12} = 4096$ discrete voltage (or current) levels.

Settling Time: The time from a change in input code until a DAC's output signal remains within $\pm \frac{1}{2}$ LSB (or some other specified tolerance) of the final value.

Definition of Terms D/A Converters

Conversion Time: The time required for a complete measurement by an analog-to-digital converter.

DC Common-Mode Error: This specification applies to ADCs with differential inputs. It is the change in the output code that occurs when the analog voltages on the two inputs are changed by an equal amount. It is expressed in LSBs.

Differential Nonlinearity: Ideally, any two adjacent digital codes correspond to measured analog voltages that are exactly one LSB apart. Differential non-linearity is a measure of the worst case deviation from the ideal 1 LSB step. For example, a DAC with a 1.5 LSB output change for a 1 LSB digital code change exhibits $\frac{1}{2}$ LSB differential non-linearity. Differential non-linearity may be expressed in fractional bits or as a percentage of full scale. A differential non-linearity greater than 1 LSB will lead to a non-monotonic transfer function in a DAC and missing codes in an ADC.

Gain Error (Full Scale Error): For an ADC, the difference (usually expressed in LSBs) between the input voltage that should ideally produce a full scale output code and the actual input voltage that produces that code. For DACs, it is the difference between the output voltage (or current) with full scale input code and the ideal voltage (or current) that should exist with a full scale input code.

Gain Temperature Coefficient (Full Scale Temperature Coefficient): Change in gain error divided by change in temperature. Usually expressed in parts per million per degree Celsius (ppm/°C).

Integral Nonlinearity (Linearity Error): Worst case deviation from the line between the endpoints (zero and full scale). Can be expressed as a percentage of full scale or in fractions of an LSB.

LSB (Least-Significant Bit): In a binary coded system this is the bit that carries the smallest value or weight. Its value is the full scale voltage (or current) divided by 2^n , where n is the resolution of the converter.

Monotonicity: A monotonic function has a slope whose sign does not change. A monotonic DAC has an output that changes in the same direction (or remains constant) for each increase in the input code. The converse is true for decreasing codes.

MSB (Most Significant Bit): In a binary coded system this is the bit that has the largest value or weight. Its value is one half of full scale.

Multiplying DAC: In a sense, every DAC is a multiplying DAC since the output voltage (or current) is equal to the reference voltage times a constant determined by the digital input code divided by 2^n (n is the number of bits of resolution). In a two quadrant multiplying DAC the reference voltage or the digital input code can change the output voltage polarity. If both the reference voltage and the digital code change the output voltage polarity, four quadrant multiplication exists.

Offset Error (Zero Error): In a DAC, this is the output voltage that exists when the input digital code is set to give an ideal output of zero volts. In the case of an ADC, this is the difference between the ideal input voltage ($\frac{1}{2}$ LSB) and the actual input voltage that is needed to make the transition from zero to 1 LSB. All the digital codes in the transfer curve are offset by the same value. Many converters allow nulling of offset with an external potentiometer. Offset error is usually expressed in LSBs.

Power Supply Rejection (Power Supply Sensitivity): The sensitivity of a converter to changes in the dc power supply voltages.

Quantizing Error: The error inherent in all A/D conversions. Since even an "ideal" converter has finite resolution, any analog voltage that falls between two adjacent output codes will result in an output code that is inaccurate by up to $\frac{1}{2}$ LSB.

Ratiometric Operation: Many A/D applications require a stable and accurate reference voltage against which the input voltage is compared. This approach results in an **absolute conversion**. Some applications, however, use transducers or other signal sources whose output voltages are proportional to some external reference. In these **ratiometric** applications, the reference for the signal source should be connected to the reference input of the converter. Thus, any variations in the source reference voltage will also change the converter reference voltage and produce an accurate conversion.

Resolution: The smallest analog increment corresponding to a 1 LSB converter code change. For converters, resolution is normally expressed in bits, where the number of analog levels is equal to 2^n . As an example, a 12-bit converter divides the analog signal into $2^{12} = 4096$ discrete voltage (or current) levels.

Settling Time: The time from a change in input code until a DAC's output signal remains within $\pm \frac{1}{2}$ LSB (or some other specified tolerance) of the final value.

*Ambient temperature range for "M" is -55°C to $+125^{\circ}\text{C}$, "I" is -25°C to $+85^{\circ}\text{C}$ or -40°C to $+85^{\circ}\text{C}$, "C" 0°C to $+70^{\circ}\text{C}$.

Sample and Hold Definition of Terms

Acquisition Time: The time required to acquire a new analog input voltage with an output step of 10V. Note that acquisition time is not just the time required for the output to settle, but also includes the time required for all internal nodes to settle so that the output assumes the proper value when switched to the hold mode.

Aperture Time: The delay required between "Hold" command and an input analog transition, so that the transition does not affect the held output.

Dynamic Sampling Error: The error introduced into the held output due to a changing analog input at the time the hold command is given. Error is expressed in mV with a given hold capacitor value and input slew rate. Note that this error term occurs even for long sample times.

Gain Error: The ratio of output voltage swing to input voltage swing in the sample mode expressed as a percent difference.

Hold Settling Time: The time required for the output to settle within 1 mV of final value after the "hold" logic command.

Hold Step: The voltage step at the output of the sample and hold when switching from sample mode to hold mode with a steady (DC) analog input voltage. Logic swing is 5V.

Audio Circuits Definition of Terms

Amplifier

Class A

A class A transistor audio amplifier refers to an amplifier with a single output device that has a collector flowing for the full 360° of the input cycle.

Class B

The most common type of audio amplifier that basically consists of two output devices each of which conducts for 180° of the input cycle.

Class C

In a class C amplifier the collector current flows for less than 180°. Although highly efficient, high distortion results and the load is frequently tuned to minimize this distortion (primarily used in R.F. power amplifiers).

Class D

A switching or sampling amplifier with extremely high efficiency (approaching 100%). The output devices are used as switches, voltage appearing across them only while they are off, and current flowing only when they are saturated.

Crossover Distortion

Distortion caused in the output stage of a class B amplifier. It can result from inadequate bias current allowing a dead zone where the output does not respond to the input as the input cycle goes through its zero crossing point. Also for I/Cs an inadequate frequency response of the output PNP device can cause a turn-on delay giving crossover distortion for negative going transition through zero at the higher audio frequencies.

Dolby B

Dolby B is a simplified version of the Dolby A professional quality noise reduction system. The amplitude of low level signals over a selected frequency range is increased prior to recording to enhance them above tape noise. On playback the original levels are restored causing a corresponding reduction in the audible tape noise. The major difference with Dolby A which used four frequency bands, is the use of a single variable frequency band with a cut-off frequency that increases in the presence of high level high frequency signals.

Dolby Level

Because of the complementary nature of the Dolby B noise reduction system, the audio channel between the encoder and the decoder must have a fixed gain such that the decoding signal level is within 2 dB of the encoding signal level. Also if recordings are interchangeable the signals in the noise reduction system must be related to the levels in

the audio channel. Dolby level provides this reference and corresponds to a specified tape flux density when recorded with a 400 Hz tone. For reel to reel and eight track cartridge tapes this is 185 nWb/m, and for cassettes Dolby level is 200 nWb/m.

Large-Signal Voltage Gain

The ratio of the output voltage swing to the change in input voltage required to drive the output from zero to this voltage.

Output Resistance

The ratio of the change in output voltage to the change in output current with the output around zero.

Output Voltage Swing

The peak output voltage swing, referred to zero, that can be obtained without clipping.

Power Bandwidth

The power bandwidth of an audio amplifier is the frequency range over which the amplifier voltage gain does not fall below 0.707 of the flat band voltage gain specified for a given load and output power.

Power bandwidth also can be measured by the frequencies at which a specified level of distortion is obtained while the amplifier delivers a power output 6 dB below the rated output. For example, an amplifier rated at 60 watts with $\leq 0.25\%$ THD, would make its power bandwidth measured as the difference between the upper and lower frequencies at which 0.25% distortion was obtained while the amplifier was delivering 30 watts.

Power Supply Rejection

The ratio of the change in input offset voltage to the change in power supply voltages producing it.

Slew Rate

The internally limited rate of change in output voltage with a large amplitude step function applied to the input.

Supply Current

The current required from the power supply to operate the amplifier with no load and the output at zero.

Thermal Resistance (R_{TH})

An analogy for heat transfer where the ability of a heat conductive system to transfer heat is described in similar terms to those used in an electrical system for power dissipated in a resistor with a given applied voltage. The thermal resistance is given by the temperature differential established when a given amount of power is being dissipated ($\theta = T_1 - T_2/P_D$) with units of °C/watt.

Radio Circuits Definition of Terms

AGC dc Output Shift: The shift of the quiescent IC output voltage of the AGC section for a given change in AGC central voltage.

AGC Figure of Merit: The widest possible range of input signal level required to make the output signal drop by a specified amount from the specified maximum output level. Typical F.O.M. numbers are from 40 dB to 50 dB, for domestic radios and about 60 dB for automotive radios (for -10 dB output level change).

AGC Input Current: The current required to bias the central voltage input of the AGC section.

AM Rejection Ratio: The ratio of the recovered audio output produced by a desired FM signal of specified level and deviation to the recovered audio output produced by an unwanted AM signal of specified amplitude and modulating index.

Channel Separation: The level of output signal of an undriven amplifier with respect to the output level of an adjacent driven amplifier.

Detection Bandwidth: That frequency range about the free running frequency of the tone decoder/phase locked loop where a signal above a specified level will cause a detected signal condition at the output.

Detection Bandwidth Skew: The measure of how well the detection bandwidth is centered about the free running frequency. It is equal to the maximum detection bandwidth frequency plus the minimum detection bandwidth frequency minus twice the free running frequency.

Hold In Range: That range of frequencies about the free running frequency for which the phase locked loop will stay in lock if initially starting out in lock.

Input Resistance: The ratio of the change in input voltage to the change in input current on either input with the other grounded.

Input Sensitivity: The minimum level of input signal at a specified frequency required to produce a specified signal-to-noise ratio at the recovered audio output.

Input Voltage Range: The range of voltages on the input terminals for which the amplifier operates within specifications.

Large-Signal Voltage Gain: The ratio of the output voltage swing to the change in input voltage required to drive the output from zero to this voltage.

-3 dB Limiting Sensitivity: In FM the input signal level which causes the recovered audio output level to drop 3 dB from the output level with a specified large signal input.

Lock In Range: That range of frequencies about the free running frequency for which the phase locked loop will come into lock if initially starting out of lock.

Maximum Sweep Rate: The maximum rate that the VCO may be made to vary its oscillating frequency over its Sweep Range.

Output Resistance: The ratio of the change in output voltage to the change in output current with the output around zero.

Output Voltage Swing: The peak output voltage swing, referred to zero, that can be obtained without clipping.

Phase Detector Sensitivity: The change in the output voltage of the phase detector for a given change in phase between the two input signals to the phase detector.

Power Bandwidth: The power bandwidth of an audio amplifier is the frequency range over which the amplifier voltage gain does not fall below 0.707 of the flat band voltage gain specified for a given load and output power.

Power bandwidth also can be measured by the frequencies at which a specified level of distortion is obtained while the amplifier delivers a power output 6 dB below the rated output. For example, an amplifier rated a 60W with $\leq 0.25\%$ THD, would make its power bandwidth measured as the difference between the upper and lower frequencies at which 0.25% distortion was obtained while the amplifier was delivering 30W.

Power Supply Rejection: The ratio of the change in input offset voltage to the change in power supply voltages producing it.

Slew Rate: The internally limited rate of change in output voltage with a large amplitude step function applied to the input.

Supply Current: The current required from the power supply to operate the amplifier with no load and the output at zero.

Sweep Range: That ratio of maximum oscillating frequency to minimum operating frequency produced by varying the central voltage of the VCO from its maximum value to its minimum value with fixed values of timing resistance and capacitance.

VCO Sensitivity: The change in operating frequency for a given change in VCO central voltage.

Video Definition of Terms

Aspect Ratio: The ratio of picture width to picture height. For the NTSC system this is 4:3.

Back Porch: The section of the composite video signal between the trailing edge of the line (horizontal) sync pulse and the end of the blanking pulse period (when picture information begins). For a monochrome signal the back porch is simply at the blanking level. For a color signal, the color burst is added within this section.

Black Level: The DC voltage level in the picture signal which corresponds to beam cut-off on the display tube. It can be at the blanking level (given by the back porch) or slightly higher (7.5% to 10% of the peak white signal above the blanking level).

Blacker-than-Black: The amplitude region in the composite video signal that extends below the reference black level in the direction of the synchronizing pulses.

Blanking: A portion of the composite video signal whose instantaneous amplitude makes the vertical and horizontal scan retrace not visible on the display tube.

Blanking Level: The level of the front and back porches of the composite video signal.

Blanking Period: The period in the composite video signal where the level is reduced to the blanking level, below which the display electron beam is cut-off. This allows non-visible retrace of the beam from the right side of the display to the left side at the end of each scan line (horizontal blanking) and non-visible return of the electron beam from the bottom of the display to the top. Horizontal blanking occurs for approximately 11 μ s between each scan line and vertical blanking for 1.2 ms between each field.

Blooming: Defocussing of the picture in regions where the brightness is too high.

Breezeway: The section in the signal blanking period between the end of the sync pulse and the start of the color burst.

C.C.I.R.: International Radio Consultative Committee—a worldwide standards organization.

Chrominance Signal: That part of the NTSC signal that contains the color information.

Clamping: A process that established a fixed DC voltage level for the picture signal. This is important for proper RF modulation and for maintaining the correct picture black level.

Color: An attribute of an object being scanned that distinguishes it from other objects, apart from shape, texture, and brightness. In television systems the color of an object is further subdivided into hue (tint) and saturation. The hue or tint refers to the dominant wavelength of a spectral color, i.e., light red is the same hue as deep red and dark red.

Deep red has more vividness or saturation (less white), whereas dark red has less brightness. Similar terms are used to describe non-spectral colors (a mixture of hues).

Color Burst: Normally refers to approximately 9 cycles of the 3.58 MHz subcarrier superimposed on the back porch of the composite video signal. The phase of this burst establishes the reference color phase for tint or hue, and the amplitude provides a reference for the color saturation level.

Color Subcarrier: A subcarrier at 3.579545 MHz (NTSC) whose modulation sidebands are added to a monochrome video signal to convey the color information. Similar subcarriers are used for SECAM and PAL.

Composite Video Signal: The complete video signal. For monochrome, it consists of blanking and synchronizing signals, with a picture signal representing the scene brightness. For color, an additional subcarrier is added for color synchronization and picture color content.

Compression: An undesired decrease in amplitude of one portion of the composite video signal relative to another portion.

Contrast: The range of dark and light values in a picture.

Cross-talk: An undesired signal interfering with a desired signal.

Definition: See resolution.

Differential Gain: The amplitude change in the 3.58 MHz color subcarrier as the picture signal varies from blanking to peak white level. This is the result of system non-linearities and is measured in percent change.

Differential Phase: The phase change, measured in degrees, of the 3.58 MHz color subcarrier as the picture signal varies from blanking to peak white level.

Equalizing Pulses: Pulses of one half the width of the line (horizontal) sync pulses, transmitted at twice the line rate for the three line periods before and after the field (vertical) sync pulse. They are used to help the vertical sync system of the receiver accommodate the half line difference in the number of scan lines on successive fields.

Field: One half of a complete picture interval. A field will contain either all the odd numbered scanning lines or all the even numbered scanning lines in the picture.

Field Frequency: The rate at which a complete field is scanned. For NTSC color signals this is nominally 59.94 Hz.

Fly-back: See Horizontal Retrace.

Frame: A complete picture consisting of two interlocking fields.

Frame Frequency: The rate at which a complete frame is scanned. In the U.S. this is nominally 30 frames or pictures per second.

Front Porch: The section of the composite video signal between the end of the picture information on a scan line (start of blanking) and the start of the line synchronization pulse.

Horizontal Blanking: The blanking signal at the end of each scan line that prevents the retrace of the display tube electron beam from being visible.

Horizontal Retrace: The rapid return of the scanning electron beam from the right side of the raster to the left side.

Horizontal Hum Bars: Relatively broad horizontal bars drifting slowly up the screen as a result of interference from the 60 Hz main frequency.

Hue (Tint): Describes the color that is being represented on the screen, i.e., red, blue, magenta, green, orange, etc.

Interlace: A scanning process in which each adjacent line belongs to the alternate field.

I.R.E.: Institute of Radio Engineers. Now combined with the AIEE to form the IEEE.

I.R.E. Scale: An oscilloscope scale calibrated for composite video and divided vertically into 140 units. The picture signal occupies the range from 0 to 100 with syncs in the range 0 to -40.

Luminance: The monochrome or brightness part of the color signal, composed of specific proportions of the three primary colors, red, blue, and green.

N.T.S.C.: National Television System Committee, used in reference to the system adopted for color television broadcasting in the U.S. at the end of 1953.

Noise: In a television picture, 'noise' refers to random interference producing a salt and pepper pattern over the picture. Heavy noise totally obscuring the picture is called "snow".

Overshoot: An (excessive) response to a unidirectional signal change. Overshoot is often used deliberately to enhance the luminance portion of a signal.

Pairing: A partial or complete failure of interlace in which scan lines of alternate fields fall in pairs, one on top of the other.

Pedestal Level: See Blanking Level.

Percentage Sync:

Video: The ratio in percent of the amplitude of the synchronizing pulse to the peak amplitude of the picture signal between blanking and reference white level. For a properly constituted composite video signal this is 40%.

RF: The ratio is a percent of the amplitude of the synchronizing pulse to the peak amplitude of the modulated RF signal. For correct modulation this is 25%.

P.A.L.: Phase Alternation Line. A variation of the NTSC system involving phase reversal of one of the color difference signals on a line by line basis, introduced into the U.K. and Germany in 1967.

Picture Signal: That portion of the composite video signal which is above the blanking level and contains the picture information.

Pre-emphasis: An increase in the level of a band of frequency components with respect to the remainder of the

signal. For U.S. television, the audio signal is increased at a 6 db/octave rate above 2.1 kHz.

Raster: The area on the face of the display tube that is scanned by the electron beam. This is not always entirely visible since commercial receivers employ overscan so that the edges of the raster are hidden by the faceplate.

Reference Signals: See V.I.T.S. and V.I.R.S.

Resolution (Horizontal): The amount of resolvable detail in the horizontal direction of the picture. This depends on the high frequency and phase response of the transmission system and the receiver.

Resolution (Vertical): The amount of resolvable detail in the vertical direction of the picture. This depends primarily on the number of scan lines that are used and secondarily on the size (shape) of the electron scanning beam.

Saturation (Color): The amplitude of the chrominance signal. Increased saturation means increased chrominance signal level. Visibly, this refers to a color increasing from pale or pastel to deep.

S.E.C.A.M.: Sequential Couleur Avec Memoire. The color broadcasting system used predominantly in France which utilizes sequential transmission of the color difference signals, which are FM modulated on two separate subcarriers (1967).

Setup: The difference in level between the blanking level and the reference black level expressed as a percent of the reference white level.

Smear: Smear describes a picture condition where objects appear extended in the horizontal direction producing an ill-defined, blurry picture. This often occurs when the receiver is tuned slightly above the proper pix carrier frequency.

Sync: Abbreviation for synchronizing or synchronization.

Sync Level: The level of the synchronizing pulse tips.

Vertical Blanking: The blanking signal at the end of each field starting three lines before the vertical sync pulse.

Vertical Retrace: The return of the electron beam from the bottom of the display to the top after a complete field has been scanned.

V.I.R.S.: Vertical Interval Reference Signal. A quality control signal added to a horizontal scan line during the vertical blanking period. It is used to provide a chrominance, luminance and black level reference.

V.I.T.S.: Vertical Interval Test Signals. A series of test signals that are added to horizontal lines during the vertical blanking for in-service testing of the transmission equipment. They can be deleted or added at various points in the transmission link, unlike the V.I.R.S., which is added at program origination and stays with the program material.

Vestigial Sideband Transmission: A broadcast transmission technique wherein only one side band of an amplitude modulated carrier is fully transmitted with the other sideband (usually lower) truncated.

Video: The visible portion of the transmitted signal representing the picture.

Video Selection Guide

VIDEO AMPLIFIERS

	Bandwidth	Gain	Package	Supply Voltage	Comments
LM592	120 MHz	100, 400	14 Pin DIP 14 Pin SO	$\pm 3V - \pm 6V$	Differential IN, Differential OUT

PLL's AND TONE DECODERS

General purpose PLL's and tone decoders are available for applications that include FSK demodulation, tone decoding, SAP and SCA demodulation, and telemetry reception. Both bipolar and CMOS devices are offered. Special purpose PLL's for TV synchronization and FM stereo demodulation are also available for use in other low frequency signal processing applications.

PLL and Tone Decoder Selection Guide

	LM565	LM567	LMC567* (CMOS LM567)	LMC568	LM1391	LM1800, LM1870, LM4500A
Typical Application	PLL	Tone Decoder	Tone Decoder	PLL	TV—Horizontal PLL	FM Stereo Demodulator PLL
Center Frequency Range	15 Hz–500 kHz	0.01 Hz–500 kHz	0.01 Hz–500 kHz	0.01 Hz–500 kHz		
VCO Control Range	±30%	±7%	±7%	±30%	±300 Hz	
Supply Voltage	±5V to ±12V	4.75V–9V	2V–9V	2V–9V	8V–9.2V	Lowest: 7V Highest: 16V (See Datasheets)
Supply Current (Typ)	8 mA	12 mA	0.8 mA	1.2 mA	20 mA	Lowest: 21 mA Highest: 45 mA (See Datasheet)

*The CMOS LMC567 oscillator runs at twice the frequency of the bipolar LM567 oscillator. Refer to the datasheets for additional information.

POWER LINE CARRIER

The LM2893/LM1893 Carrier-Current Transceiver performs as a power line interface for half-duplex (bi-directional) communication of serial bit streams of virtually any coding. Applications include energy management systems, inter-office control, fire alarm systems, security systems, telemetry, and remote meter reading.

TIMERS

General purpose timers are available for generating accurate time delays or oscillation. Both bipolar and CMOS devices are offered.

Timer Selection Guide

	LM322	LM2905	LM555	LMC555* (CMOS LM555)	LM556 (Dual LM555)
Trigger Pulse Relative to Output Pulse	Can Be Longer	Can Be Longer	Must Be Shorter	Must Be Shorter	Must Be Shorter
Typical Application	Monostable	Monostable	Astable	Astable	Astable
Supply Voltage	4.5V–40V	4.5V–40V	4.5V–15V	1.2V–12V	4.5V–15V
Supply Current (Typical)	2.5 mA	2.5 mA	10 mA	0.15 mA	10 mA (Each Timer Section)

*The CMOS LMC555 can handle -10 mA to $+50\text{ mA}$ of output current and the bipolar LM555 can handle up to $\pm 200\text{ mA}$ of output current.

VCO AND FUNCTION GENERATOR

The LM566 is a general purpose voltage controlled oscillator which may be used to generate square and triangle waves. Typical applications include FM modulation, signal generation, function generation, frequency shift keying, and tone generation. The LM566 has very linear modulation characteristics.

Drive-Related Building Blocks

DISPLAY DRIVERS

LED flasher/oscillator and dot/bar display drivers are offered.

Display Driver Selection Guide

	LM3909	LM3914	LM3915	LM3916
Typical Application	Flasher/ Oscillator	Dot/Bar Display Driver	Dot/Bar Display Driver	Dot/Bar Display Driver
Display Scale	N/A	Linear	Log	VU Meter
Display Type	LED, Incandescent	LED, LCD, Vacuum Fluorescent	LED, LCD, Vacuum Fluorescent	LED, LCD, Vacuum Fluorescent

METER DRIVERS

The LM1819 Air-Core Meter Driver is a function generator/driver for air-core (moving-magnet) meter movements in tachometers and ruggedized instruments. Driver outputs are self-centering and better than 2% linearity is guaranteed over a full 305° deflection range. Signal conditioning circuitry is included on chip.

TEMPERATURE CONTROLLER

The LM3911 (Note 1) is a temperature controller containing a precision temperature sensor, op amp, and reference. It is designed for temperature sensing and closed loop temperature control applications over the -25°C to $+85^{\circ}\text{C}$ range.

Note 1: See Linear 2 for datasheet.

Precision-Related Building Blocks

CHOPPER BLOCK

The LMC669 Auto Zero Block (Note 1) is a universal commutating auto-zero block that can be used with any operational amplifier to correct offset voltage.

Note 1: See Linear 2 for datasheet.

TRANSISTOR ARRAYS

A variety of matched and power transistors are offered.

Transistor Array Selection Guide

	LM394	LM395	LM3046	LM3146
Description	NPN Transistor Pair	Power Transistor	5 NPN Transistors	5 NPN Transistors
Key Features	<ul style="list-style-type: none"> • Emitter-Base Voltage Matched to 50 μV • Current Gain Matched to 2% 	<ul style="list-style-type: none"> • Collector Current: 1A • Quiescent Current: 10 mA • Switching Time: 2 μs • Current Limit • Thermal Limit • Safe Area Protection 	<ul style="list-style-type: none"> • Emitter-Base Voltage Matched to ± 5 mV • Breakdown Voltages <ul style="list-style-type: none"> —$V_{(BR)(CBO)}$: 20V —$V_{(BR)(CEO)}$: 15V —$V_{(BR)(CLO)}$: 20V —$V_{(BR)(EBO)}$: 5V • DC—120 MHz 	<ul style="list-style-type: none"> • Emitter-Base Voltage Matched to ± 5 mV • Breakdown Voltages <ul style="list-style-type: none"> —$V_{(BR)(CBO)}$: 40V —$V_{(BR)(CEO)}$: 30V —$V_{(BR)(CLO)}$: 40V —$V_{(BR)(EBO)}$: 5V • DC—120 MHz

Sensing-Related Building Blocks

LIQUID LEVEL SENSORS

A variety of liquid level sensing circuits are offered.

Liquid Level Sensor Selection Guide

	LM903	LM1042	LM1812	LM1830
Output Type	Digital HI/LO	Analog	Pulse-Echo Timing	Digital HI/LO
Operation Method	Thermoresistive Probe	Thermoresistive Probe	Acoustic Transducer	Conductive Liquid

SPECIAL AMPLIFIERS

A variety of special sensor amplifiers are offered.

Special Amplifiers Selection Guide

	LM1815	LM1964
Typical Application	Adaptive Sense Amplifier	Sensor Interface Amplifier
Sensor	Inductive Pickup	Lambda Sensor
Key Features	<ul style="list-style-type: none"> • Operates from 2.5V to 12V Supply • Adaptive Hysteresis • True Zero Crossing Timing Reference 	<ul style="list-style-type: none"> • Normal Operation Guaranteed with Inputs up to 3V Below Ground on a Single Supply • Fully Protected Inputs • Input Open Circuit Detection

SPECIAL COMPARATOR

The LM1801 Battery Operated Power Comparator is an extremely low power comparator with a high current, open collector output stage. Typical applications include intrusion alarms, water leak detectors, gas leak detectors, overvoltage crowbars and battery operated monitors. The LM1801 is designed to operate in a standby mode for 1 year, powered by a 9V alkaline battery.

SPECIAL CONVERTERS

A variety of special converters for signal transformation applications are offered.

Special Converters Selection Guide

	LH0091 (Note 1)	LH0094 (Note 1)	LM331 (Note 1)	LM2907, LM2917
Converter Type	True RMS-to-DC	Multifunction	Voltage-to-Frequency	Frequency-to-Voltage
Key Features	<ul style="list-style-type: none"> • 0.1% Accuracy with External Trim • Uncommitted Amplifier for Filtering, Gain or High Crest Factor Configuration • True RMS Conversion 	<ul style="list-style-type: none"> • $OUT = IN_Y \left(\frac{IN_Z}{IN_X} \right)^m$, $0.1 \leq m \leq 10$, m Continuously Adjustable • Applications <ul style="list-style-type: none"> —Precision Divider, —Multiplier —Square Root —Square —Trigonometric Function Generator —Companding —Linearization —Control Systems —Log Amp 	<ul style="list-style-type: none"> • 1 Hz to 100 kHz Frequency Range • Split or Single Supply Operation 	<ul style="list-style-type: none"> • Operates Relay, Lamp or Other Load when Input Exceeds a Selected Rate • Ground Referenced Tachometer Fully Protected from Damage Due to Swings Above Supply or Below Ground

Note 1: See Linear 2 for datasheets.

ULTRASONIC TRANSCIEVER

The LM1812 Ultrasonic Transceiver is a general purpose ultrasonic transceiver designed for use in a variety of ranging, sensing, and communications applications. Typical uses include liquid level measurement, sonar, surface profiling, data links, hydro-acoustic communications, non-contact sensing and industrial process control. Depending on the acoustic transducer, typical performance capabilities include 5 feet to 100 feet in water and 4 inches to 35 feet in air.

Voltage Regulators Definition of Terms

Current-Limit Sense Voltage: The voltage across the current limit terminals required to cause the regulator to current-limit with a short circuited output. This voltage is used to determine the value of the external current-limit resistor when external booster transistors are used.

Dropout Voltage: The input-output voltage differential at which the circuit ceases to regulate against further reductions in input voltage.

Feedback Sense Voltage: The voltage, referred to ground, on the feedback terminal of the regulator while it is operating in regulation.

Input Voltage Range: The range of dc input voltages over which the regulator will operate within specifications.

Line Regulation: The change in output voltage for a change in the input voltage. The measurement is made under conditions of low dissipation or by using pulse techniques such that the average chip temperature is not significantly affected.

Load Regulation: The change in output voltage for a change in load current at constant chip temperature.

Long Term Stability: Output voltage stability under accelerated life-test conditions at 125°C with maximum rated voltages and power dissipation for 1000 hours.

Maximum Power Dissipation: The maximum total device dissipation for which the regulator will operate within specifications.

Output-Input Voltage Differential: The voltage difference between the unregulated input voltage and the regulated output voltage for which the regulator will operate within specifications.

Output Noise Voltage: The RMS ac voltage at the output with constant load and no input ripple, measured over a specified frequency range.

Output Voltage Range: The range of regulated output voltages over which the specifications apply.

Output Voltage Scale Factor: The output voltage obtained for a unit value of resistance between the adjustment terminal and ground.

Quiescent Current: That part of input current to the regulator that is not delivered to the load.

Ripply Rejection: The line regulation for ac input signals at or above a given frequency with a specified value of bypass capacitor on the reference bypass terminal.

Standby Current Drain: That part of the operating current of the regulator which does not contribute to the load current. (See Quiescent Current)

Temperature Stability: The percentage change in output voltage for a thermal variation from room temperature to either temperature extreme.

Thermal Regulation: Percentage change in output voltage for a given change in power dissipation over a specified time period.

HS7067/HS7107 7 Amp, Multimode, High Efficiency Switching Regulator

General Description

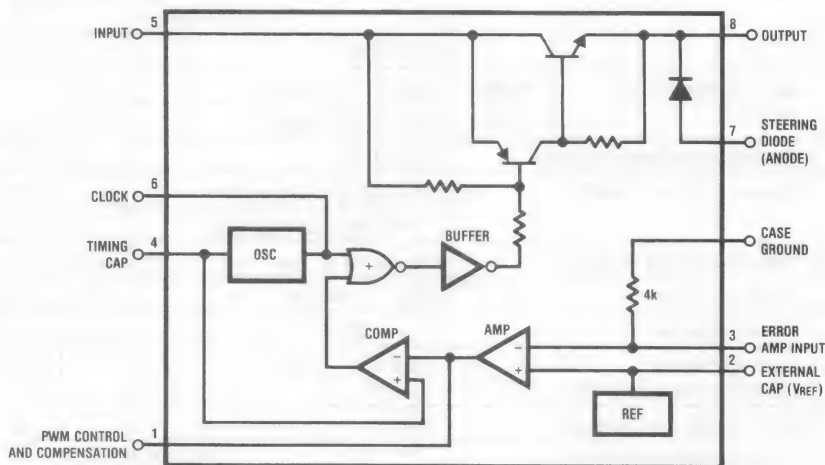

The HS7067/HS7107 is a hybrid high efficiency switching regulator with high output current capability. The device is housed in a standard TO-3 package containing a temperature compensated voltage reference, a pulse-width modulator with programmable oscillator frequency, error amplifier, high current, high voltage output switch and steering diode. The HS7067/HS7107 operates in a step-down, inverting, as well as in a transformer-coupled mode.

The HS7067/HS7107 can supply up to 7A of continuous output current over a wide range of input and output voltages.

Features

- HS7067—10V to 60V input
- HS7107—10V to 100V input
- 7A continuous output current
- Step-down, inverting, and transformer-coupled operation
- Frequency adjustable to 200 kHz
- High-efficiency (>75%)
- Standard 8-pin TO-3 package

Typical Applications

THE BUCK CONVERTER (Step Down)

The buck converter is the most common application in switching-power conversion. It allows to step down a voltage with a minimum of components and a maximum of efficiency (for further information on the theory of operation of a buck converter, see AN-343).

f_O	25 kHz	200 kHz
L	$86\ \mu\text{H}$	$21\ \mu\text{H}$

Typical Applications (Continued)

Design equations:

Following are the design equations for a buck converter application using the HS 7107/7067:

$$C_T = \frac{1}{10^4 \times f_O}$$

$$L_{MIN} = \frac{(V_{IN(MAX)} - V_O) V_O}{V_{IN(MAX)} \times f_O \times \Delta I} \quad (\text{Note 7, 9})$$

$$C_{MIN} = \frac{\Delta I}{4 f_O (e_O - \Delta I \times ESR)} \quad (\text{Note 8, 9})$$

$$C_C = \frac{\sqrt{10 LC}}{R_C}$$

$$R_C = \frac{2 \times 10^5}{V_{IN(MAX)}}$$

$$R_f = 4k \left(\frac{V_O - 2.5}{2.5} \right) \Omega$$

Note 7: L_{MIN} is the minimum value of output filter inductance, L, for stable operation.

Note 8: C_{MIN} is the minimum value of output filter capacitance, C, necessary to achieve an output ripple voltage, e_O . ESR is the Effective Series Resistance of the output filter capacitor, C, at the operating frequency, f_O .

Note 9: ΔI = Peak to Peak Ripple current through the inductor and the capacitor. $\frac{\Delta I}{2} < I_{O\ MIN}$ and $\frac{\Delta I}{2} < 7 - I_{O\ MAX}$.

Efficiency Equations

Since high efficiency is the principal advantage of switched-mode power conversion, switching regulator losses are an important design concern. Losses and efficiency of a buck converter can be calculated with the following equations.

Note: Pin 7 is grounded; I_O = average output current at pin 8

Switching Period (T)

$$T = \frac{1}{f_O} = t_{ON} + t_{OFF}$$

Duty Cycle (D)

$$D = \frac{t_{ON}}{t_{ON} + t_{OFF}} = \frac{V_O + V_F}{V_{IN} - V_S + V_F}$$

Transistor DC Losses (P_T)

$$P_T = V_S \times I_O \times D$$

Transistor Switching Losses (P_S)

$$P_S = (V_{IN} + V_F) \times I_O \times \frac{(t_r + t_f + 2t_s) f_O}{2}$$

Capacitor Losses (P_C)

$$P_C = ESR \times \left(\frac{V_O (T - DT)}{4L} \right)^2$$

Diode DC Losses (P_D)

$$P_D = V_f \times I_O \times (1 - D)$$

Drive Circuit Losses (D_L)

$$D_L = 0.02 \times V_{IN} \times D$$

Inductor Losses (P_L)

$$P_L = I_O^2 \times R_L \text{ (DC winding resistance)}$$

Power Output (P_O)

$$P_O = \frac{((V_{IN} - V_S) t_{ON}) - ((V_F) t_{OFF})}{t_{ON} + t_{OFF}} \times I_O$$

Efficiency (η)

$$\eta = \frac{P_O}{P_{IN}} = \frac{P_O}{P_O + P_T + P_S + P_D + D_L + P_L + P_C}$$

TRANSFORMER COUPLED CONVERTERS

In addition to the implementation of a buck converter, the HS 7107/7067 can be used in various transformer coupled configurations. They can be used in various topologies such as: step-up, step-down, inverter, multiple outputs and isolated converters.

There are basically two different methods in implementing transformer coupled converters: the flyback and the forward topology

The Flyback Principle

Figure 1 shows a functional diagram of a flyback converter. Depending on the turn ratio N_2/N_1 and the feedback voltage, it can be implemented as a step-down or step-up converter.

When the switch is on, the current (I_p) flows through the primary winding creating a magnetic flux in the core and storing the energy. At this time, the voltage at the secondary keeps the same polarity (with respect to the dotted terminals), the diode is off and no current flows through it. When the switch is off, the voltage at the secondary and primary becomes reversed and the diode turns-on (I_d). The stored energy is then transferred to the load and the output filter capacitor. The energy stored in the capacitor will supply the load current during the next turn-on.

FIGURE 1. Typical Flyback Functional Diagram

TL/K/6746-5

Typical Applications (Continued)

- V_p = Voltage at primary
- V_{as} = Voltage across the switch
- V_s = Voltage at the secondary
- I_p = Current at primary
- I_d = Current through diode
- I_c = Current through output cap
- I_{out} = Output current of the converter
- ΔI = Ripple current
- D = $T_{on}/(T_{off} + T_{on})$
- F = Switching frequency
- V_{df} = Forward voltage drop of the diode
- $V_1 = V_{out} \times N_1/N_2$ $V_2 = V_{in} + V_{out} N_1/N_2$
- V_3 = Saturation voltage of the switch
- $V_4 = V_{out} + V_{df}$ $V_5 = V_{in} \times N_2/N_1$

TL/K/6746-6

FIGURE 2. Typical Flyback Waveforms

The load current is not supplied directly by the input source when the switch is on, but only by the energy stored in the output capacitor. The output voltage is monitored by the feedback loop which controls the duty cycle (D) through the PWM (Pulse Width Modulator) which in turn, modulates the amount of energy being transferred from the input to the output. Figure 2 shows the waveforms of a continuous mode flyback converter (primary current I_p is DC biased).

The Forward Principle

The forward converter is a little more complex and requires more components than the flyback, but the output ripple voltage is smaller. Figure 3 shows a simplified diagram of a forward converter.

When the switch turns-on, a voltage $V_5 = V_1 \times N_2/N_1$ appears at the secondary of the transformer. The diode D_2

TL/K/6746-7

FIGURE 3. Typical Forward Functional Diagram

Typical Applications (Continued)

is off while D_1 turns-on, allowing the current to flow through the inductor L (I_{d1} and I_L), storing energy in its core, and supplying the load current (I_{out}) and the capacitor current (I_C) at the same time. When the switch turns-off, the magnetic energy stored in the core of the inductor creates a current (I_{d2}) which flows through the diode D_2 . The load current I_{out} therefore, equals to $I_{d2} + I_C$.

During the "off" time of the switch, some residual magnetism will stay in the core of the transformer and has to be removed before the next cycle, so that it does not accumulate, leading to core saturation.

A demagnetizing winding is used to "dump" the residual energy back to the input or output of the converter. The

functional principle of the demagnetizing winding is similar to the flyback in the sense that, during the turn-off time, the residual magnetism will generate a reverse voltage at the demagnetizing winding (with respect to the dotted terminals) turning on the diode D_3 .

In the forward mode, when the switch is off, the load current is supplied by the energy stored in the output capacitor and the choke inductor but when the switch is on, it is supplied by the input source through the transformer. This accounts for the lower output ripple voltage.

The output voltage is monitored by the feedback loop, which controls the duty cycle through the PWM, which in turn modulates the amount of energy being transferred from the input to the output.

- V_p = Voltage at primary
- V_{as} = Voltage across the switch
- V_s = Voltage at secondary
- I_p = Current at primary
- I_{d1} = Current through diode D_1
- I_{d2} = Current through diode D_2
- I_{d3} = Current through diode D_3
- I_L = Current through inductor L
- I_C = Current through output cap
- I_{out} = Output current of the converter
- ΔI = Ripple current
- F = Switching frequency
- D = $T_{on} / (T_{off} + T_{on})$
- $V_1 = V_{in} \times N_1/N_3$ $V_3 = V_{in}$
- $V_2 = V_{in} + V_1$
- V_4 = Saturation voltage of the switch
- $V_5 = V_{in} \times N_2/N_1$ $V_6 = V_{in} \times N_2/N_3$

Figure 4 shows the waveforms of the forward converter.

When the switch is off, $V_{as} = V_{in} + (V_{in} \times N_1/N_3)$ during the demagnetization time (T_d) and then, drops to $V_{as} = V_{in}$ as indicated in Figure 4.

FIGURE 4. Typical Forward Waveforms

TL/K/6746-8

Typical Applications (Continued)

With both flyback and forward topologies, it is possible to design an inverting converter by using an external op-amp (Figure 5).

TL/K/6746-10

FIGURE 5

Flyback Step-Up Application

Figure 6 shows flyback converter in a step-up mode where an input voltage of +12V to +30V will be converted into a regulated output voltage of +50V.

Performance Data

Parameter	Conditions	Result
Efficiency	$V_{out} = 50V @ 300\text{ mA}$ $V_{in} = 15V$	82%
Line Regulation	$V_{out} = 50V @ 300\text{ mA}$ $12V \leq V_{in} \leq 30V$	0.2%
Load Regulation	$V_{in} = 15V$ $V_{out} = 50V$ $50\text{ mA} \leq I_{out} \leq 300\text{ mA}$	0.2%

Isolated Flyback Converter

Figure 7 shows an isolated flyback converter using a sense winding for feedback. Although, in practice the line regulation is acceptable, the load regulation can be marginal if the coupling between the windings is poor. However, the sense winding cannot detect any ohmic voltage drop in the main output so, a heavier gauge wire should be used to reduce this regulation error. Also, the sense winding will not sense the non-linear voltage drop across the diode, and this accounts for most of the load regulation inaccuracy. Therefore, the sense winding method is only recommended for applications where load variations are small.

Figure 7 shows an isolated flyback converter with an output of 5V at 2A. The input voltage range is from +10V to +40V. The output can be adjusted to +5V by using the 5 k Ω trimpot.

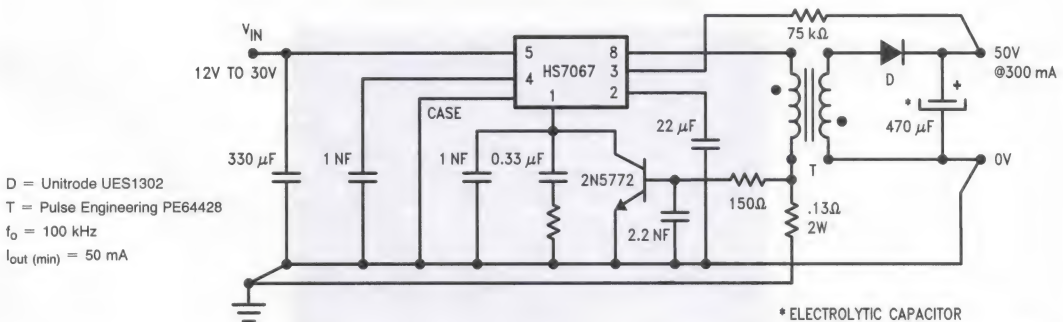

Performance Data

Parameter	Conditions	Result
Efficiency	$V_{out} = 5V @ 2A$ $V_{in} = 30V$	75%
Line Regulation	$V_{out} = 5V @ 2A$ $10V \leq V_{in} \leq 40V$	5%
Load Regulation	$V_{in} = 30V$ $1A \leq I_{out} \leq 2A$	7%

Isolated Forward Converter

As described previously, forward converters exhibit lower output ripple voltage and the opto-coupler feedback scheme provides good regulation as well as input to output isolation.

An opto-coupler feedback is usually difficult to implement because the transfer function of the opto-coupler is non-linear, the current transfer ratio changes with time and temperature and also from one unit to another. Figure 8 shows the circuit diagram of a 5V @ 3A power converter with an input voltage range of +14V to +30V using an isolated forward topology.

D = Unitrode UES1302
T = Pulse Engineering PE64428
 $f_o = 100\text{ kHz}$
 $I_{out}(\text{min}) = 50\text{ mA}$

*ELECTROLYTIC CAPACITOR

TL/K/6746-11

A 12V to 60V input Voltage Range is possible by replacing the HS7067 with a HS7107. The converter will operate in a discontinuous mode above 30V with a 300 mA load (the transformer's secondary current drops to zero before the switch turns on) and therefore, may generate more switching noise.

FIGURE 6. Flyback Step-Up Converter

Typical Applications (Continued)

- D₁ = International Rectifier 50SQ060
- D₂ = 1N4148
- I_{out} (min) = 1A
- f_O = 100 kHz
- T = Transformer made of a core Fenoxcube 1811PA2503B7
- Primary = 8 turns with 5 strands #29
- Secondary = 6 turns with 15 strands #30
- Sense = 25 turns with 1 strand #30

windings should be interleaved in order to improve the coupling and regulation.

FIGURE 7. Isolated Flyback Converter

* ELECTROLYTIC CAPACITOR

TL/K/6746-12

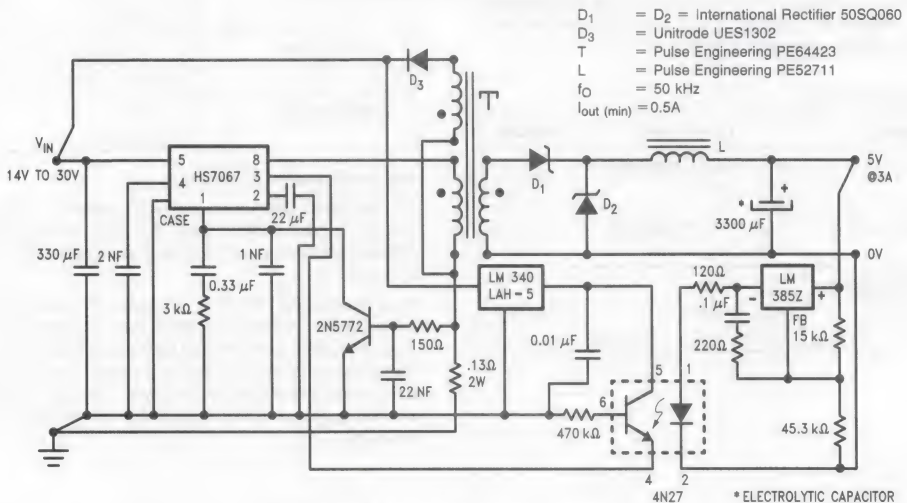

FIGURE 8a. Isolated Forward Converter

* ELECTROLYTIC CAPACITOR

TL/K/6746-13

TL/K/6746-9

Figure 8b shows the typical forward converter waveforms in continuous mode which can be observed using the circuit from Figure 8a. Top waveform is the voltage across the switch (20V/div). Bottom waveform is the current through the switch (1A/div). Horizontal Scale = 5 μS/div. V_{in} = 20V; V_{out} = 5V @ 3A.

Figure 8b.

Typical Applications (Continued)

An LM 385z (adjustable reference) is used as a comparator and error amplifier. This reference always wants to maintain 1.2V between pins 1 and 2 and will draw as much current as necessary from the opto-coupler to achieve this. Therefore, the feedback loop is virtually independent of the gain of the opto-coupler.

Performance Data

Parameter	Conditions	Result
Efficiency	$V_{out} = 5V @ 3A$ $V_{in} = 30V$	78%
Line Regulation	$V_{out} = 5V @ 3A$ $14V \leq V_{in} \leq 30V$	0.1%
Load Regulation	$V_{out} = 5V$ $V_{in} = 20V$ $0.5A \leq I_{out} \leq 3A$	0.1%

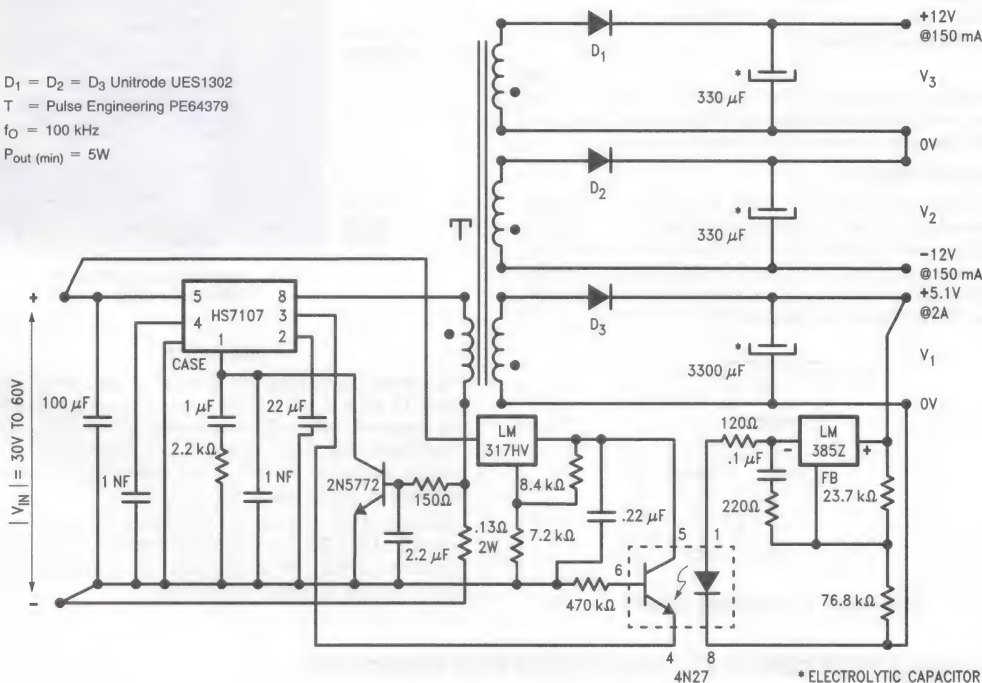

Isolated Telecom Converter

Figure 9 shows an isolated triple output converter which will transform a positive or negative input voltage of 32V to 60V to an uncommitted triple output of +12V, -12V, and 5V, which may be later referenced to the system ground. This converter is ideal for a step down converter of high positive voltage or high negative voltage such as -48V used in telecom circuits.

Performance Data

Parameter	Conditions	Result
Efficiency	$V_1 = 5.1V @ 2A$ $V_2 = -12V @ 150mA$ $V_3 = 12V @ 100mA$ $ V_{in} = 48V$	62%
Line Regulation on Main Secondary	$40V \leq V_{in} \leq 60V$ $V_1 = 5.1V @ 2A$ $V_2 = -12V @ 150mA$ $V_3 = +12V @ 150mA$	0.8%
Load Regulation on Main Secondary	$ V_{in} = 48V$ $V_1 = 5.1V$ $V_2 = 12V @ 150mA$ $V_3 = 12V @ 150mA$ $0.5 \leq I_{out} \leq 2A$	1%
Load Regulation on 12V Secondary for Simultaneous Load Changes	$ V_{in} = 48V$ $V_1 = 5.1V @ 2A$ $V_2 = -12V$ $V_3 = 12V$ $75mA \leq I_{out} \leq 150mA$	5%

$D_1 = D_2 = D_3$ Unitrode UES1302
T = Pulse Engineering PE64379
 $f_0 = 100\text{ kHz}$
 $P_{out}(\text{min}) = 5W$

Note 10: An input voltage of -10V to -30V may cause the transformer to operate at a higher temperature at full load.

TL/K/6746-14

FIGURE 9. Telecom Flyback Converter

Application Hints

DUTY CYCLE LIMITING

In a flyback converter, the error amplifier sees 0V at the output of the converter during the initial turn-on, and forces the duty cycle to 100% until it sees the output voltage rising to the final value; but no voltage will appear if the switch does not turn off (see flyback principle). The result is that the core will saturate, reducing the effective impedance of the transformer to about 0Ω , and destroying the pass transistor. To prevent this, the duty cycle must be limited to a value at which the core does not saturate. A diode connected between pins 1 and 2 (Figure 10), will limit the duty cycle to about 80%.

TL/K/6746-15

FIGURE 10. Duty Cycle Limiting Circuit

SOFT START

For any converter, connecting a large capacitor (20 to 200 μF) between pin 2 and the case is recommended to allow the reference voltage to slowly reach its final value after start-up. This allows the HS 7067/7107 to start-up smoothly and minimizes the inrush current. The time constant can be calculated by:

$$T = 10^3 \times C$$

It is always a good practice to incorporate soft start and duty cycle limiting when designing a switching power converter, especially when a current limit circuitry is not utilized.

CURRENT LIMIT

The schematic in Figure 11 shows how to protect the pass transistor against excessive current, by sensing the current through a series resistor, and shorting the PWM control voltage at pin 1 to ground, using transistor 2N5772 (this is made possible by the 5 M Ω output impedance of the error amplifier), which will cause the pass transistor to turn off.

TL/K/6746-16

FIGURE 11. Current Limit Circuitry

The sense resistor should be a low inductance type, otherwise the series inductance creates a high impedance at transients and activates the shutdown circuitry. If such a resistor cannot be found, a 0.1 μF connected in parallel with it will compensate the series inductance.

When such a circuitry is used, the duty cycle limiting diode becomes optional, but the soft start capacitor should still be at least 10 μF .

DECOUPLING AND GROUNDING

Special attention should be given to the decoupling of the HS 7107/7067 itself at the input (pin 5), where the capacitor must be at least 100 μF and connected as close to the device as possible. Large switching spikes at the input of the pass transistor can cause breakdown of the junction and destroy the device. (See Figure 12.)

The waveform at the top of the picture represents the voltage across the switch of a typical BUCK (step down) converter. When the switch is turned off, the current in the inductor falls to zero (see waveform at the bottom) and a switching spike occurs across the switch. This spike can reach several tens of volts on top of the normally expected voltage across the switch and lead to stress on the device if the overall voltage exceeds the maximum rating.

The picture below shows a spike of about ten volts with a 330 μF capacitor of average quality.

VOLTAGE ACROSS
PIN 5 & PIN 8

CURRENT
THROUGH
SWITCH

VERTICAL SCALE: 20 VOLTS/DIV
HORIZONTAL SCALE: 2 μS /DIV

TL/K/6746-17

FIGURE 12

The reference voltage (pin 2) must be decoupled with at least 10 μF and the compensation network (pin 1) should be decoupled with a ceramic capacitor of 1 nF to 10 nF. Switching noise on the reference voltage pin (pin 2) or on the compensation pin (pin 1) can create different types of oscillations and instabilities.

Because of the high current and high voltage capability of the HS 7107/7067 a single point grounding or, at least a grounding where the force ground is separated from the circuit ground, is highly recommended.

HS9151 Micro-Switching Off-Line Power Converter

120 V_{AC}/+5V @ 3 Amps

General Description

The HS9151—Micro-Switching Off-Line Power Converter is a hybrid power converter housed in a 3.5" x 1.5" x 0.44" metal dual-in-line package.

The high efficiency of the Off-Line Converter is achieved by using advanced switching technology.

A 1 MHz PWM controller with current limiting and temperature protection is incorporated in the package. Also, the input and output rectifiers and magnetics are included as well as an internally adjusted opto-isolator feedback stage.

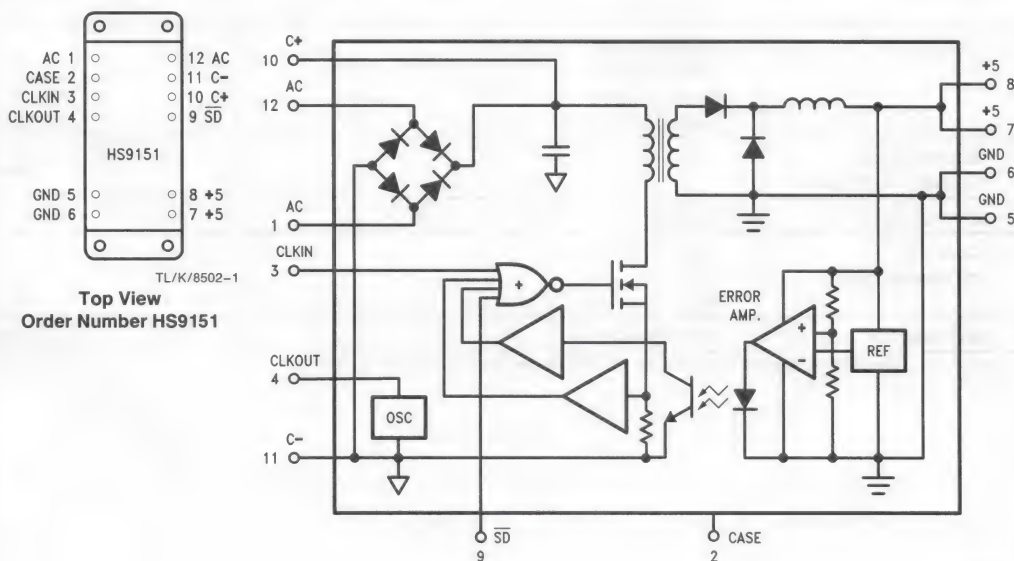

With a 120 V_{AC} nominal input voltage, the HS9151 can supply 3 amps at +5 V_{DC} over a temperature range of -25°C to +85°C and only requiring a heatsink for operation above 40°C.

The HS9151 provides access to the clock input pin for synchronization of several HS9151s from an external clock, or the internal clock of one unit can be used as a master clock for several units. The HS9151 also features softstart at power up.

Features

- 120 V_{AC} or 170 V_{DC} nominal input
- +5 V_{DC} output at 3 amps
- 3.5" x 1.5" x 0.44" size
- 1000 V_{RMS}/1500 V_{DC} Input/Output isolation
- Full 3A output current capability over temperature
- Synchronization
- Shortcircuit/temperature protection
- Softstart and remote shutdown
- 1 MHz switching frequency
- Isolated case

Block and Connection Diagrams

Note 1: Caution: this device is operated directly from the 115 Vrms AC line. An isolation transformer must be used when making measurements with test equipment, to prevent personnel exposure to lethal voltage potentials. Standard high voltage safety procedures should also be observed.

Note 2: Pin 2 is connected to case ground.

Absolute Maximum Ratings

If Military/Aerospace specified devices are required, contact the National Semiconductor Sales Office/Distributors for availability and specifications.

V_{IN} , Input Voltage	
AC Voltage (Pin 1 to Pin 12)	140 V _{AC}
DC Voltage (Pin 10 to Pin 11)	200 V _{DC}

Shutdown \overline{SD}	(See Figure 2)			2.5	V

Note 1: The output ripple is dependent on the ESL and ESR of the output filter capacitor (see Figure 4).

Typical Performance Characteristics

Note: Case temperature should not exceed 100°C.

Note: Assumes $T_{CASE} (MAX) = 100^{\circ}C$.

Application Information

IN-RUSH CURRENT LIMITING

During start up, the input of the HS9151 presents a very low impedance to the AC line, generally only the ESR of the input filter. If current limit is not provided at the input, the high in-rush current can destroy the input rectifier bridge.

A 10Ω (1 Watt) resistor should be placed in series with the input rectifier bridge and the AC line to limit the current to a non-destructive level. This scheme reduces the efficiency of the power converter by approximately 3% at full load due to the I^2R loss in the resistor (see Figure 4).

CLKIN and CLKOUT

The HS9151 provides an internal 1 MHz clock, CLKOUT (pin 4), that allows several units to be synchronized to one master clock in applications where multiple units are used. The logic high is specified at 10.0V (min.) and logic low is specified at 0.5V (max.) when $I_{OUT} = \pm 1$ mA. The CLKIN (pin 3) allows the power converter to use an

externally supplied 1 MHz clock instead of using the oscillator provided inside the HS9151. Isolation is required when using an external clock. In applications that do not require synchronization, the CLKIN and CLKOUT pins should be connected together.

Figure 1 below, shows the connection scheme when three HS9151s are synchronized off the same master clock provided by unit #1.

REMOTE SHUTDOWN \overline{SD}

A remote shutdown function (pin 9) is also provided in the HS9151. This allows the switching converter to be disabled when pin 9 is brought below 2.5 volts. This feature allows proper power up sequencing of a complex system, and it also enables peripheral equipment to be turned on and off remotely. An input equivalent circuit of the \overline{SD} pin is shown in Figure 2.

FIGURE 1. HS9151 Synchronization

TL/K/8502-4

Application Information (Continued)

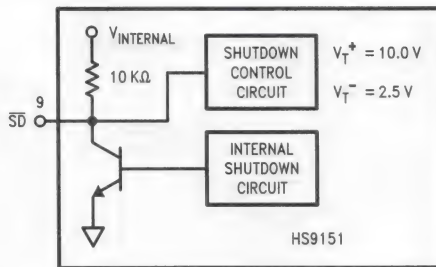

FIGURE 2. HS9151 Shutdown Block Diagram

TL/K/8502-5

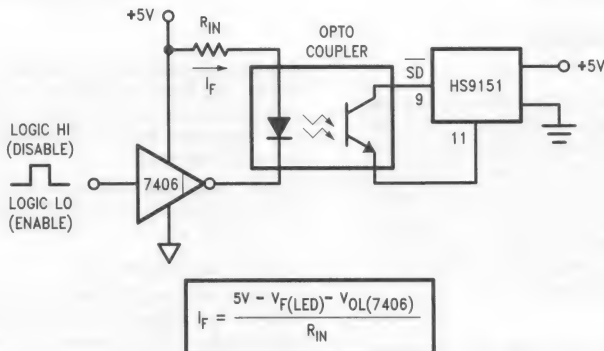

FIGURE 3. Remote Shutdown Using an Opto Coupler and +5V Logic

TL/K/8502-6

Because the shutdown control is located on the primary side of the power converter, it is recommended that the shutdown control signal, \overline{SD} , be isolated either optically or by other means. Figure 3 shows a typical implementation of the remote shutdown function, using an opto coupler for isolation.

When the shutdown feature is used in systems where multiple HS9151s are synchronized from a master clock (see Figure 1) and sequenced, the shutdown procedure should be such that the master unit is the last unit to be turned off and the first one to be turned on.

Typical Applications

The HS9151 can be configured into a complete 5V @ 3A power supply by simply adding an input capacitor and two output capacitors. Figure 4 shows an implementation using a 100 μ F input capacitor to provide a holdup time of 16 ms. A 220 μ F aluminum electrolytic capacitor in parallel with a 5 μ F low ESL capacitor guarantees loop stability under all line and load conditions. The low ESL (equivalent series inductance) capacitor also keeps the output ripple under 50 mV peak to peak. A 130 V_{AC} metal oxide varistor (MOV) is also necessary for input protection and the 10 Ω , 1 Watt resistor limits in-rush current to under 20A.

The efficiency of the power supply is a function of the input line voltage and the output load current. At maximum load current, the efficiency is the highest, approaching 75% with $V_{in} = 120$ VAC. Also, the efficiency varies by less than $\pm 2\%$ when the line voltage changes from low line to high line at maximum output load current (see graph for efficiency versus output current).

THERMAL CONSIDERATIONS

The HS9151 is housed in an all metal hybrid power package measuring only 3.5" x 1.5" x 0.44". The low thermal resistance of this package allows the power converter to operate at full power (5V at 3A) without a heatsink up to an ambient temperature of 40°C. For operation beyond 40°C, some

form of heat sinking is recommended. The rise in temperature of the internal components is dependent on the power delivered at the output. Under normal operating conditions, it is recommended that the case temperature of the HS9151 be kept below 90°C. Under these conditions, the junction temperature of the internal integrated circuits are kept below 115°C.

For selecting a proper heatsink consult the graph provided. This information greatly simplifies the task of selecting the proper heatsink for the HS9151 when it is operated at elevated temperatures. For example, when a load current of 3 amperes is drawn from the power converter, and a heatsink with a 2°C/W thermal resistance is used, the case temperature would increase by 10°C. Alternatively, if a 6°C/W heatsink were used, the case temperature would go up by 30°C.

LH0075 Positive Precision Programmable Regulator

General Description

The LH0075 is a precision programmable regulator for positive voltages. Regulated output voltages from 0 to 27V may be obtained using one external resistor. Also available without any external components are several fixed regulated voltages with accuracies to 0.1% (5V, 6V, 10V, 12V and 15V). The output current limit is adjustable from 0 to 200 mA using two external resistors. These features provide an inventory of precision regulated values in one package.

Features

- Output adjustable to 0V
- Line regulation typically 0.008%/V
- Load regulation typically 0.075%
- Remote voltage sensing
- Ripple rejection of 80 dB
- Adjustable precision current limit
- Output currents to 200 mA
- Popular voltages available without external resistors

Applications Information

The LH0075 does not require capacitors for stable operation, but an input bypass is recommended if device is far

from filter capacitors. A 0.1 μF for input bypassing should be adequate for almost all applications.

Applications Information (Continued)

DESCRIPTION OF OPTIONS

Ripple Rejection Compensation. (Increases Ripple Rejection Typically to 80 dB)

The ripple rejection may be improved by connecting an external capacitor between pin 9 and ground. (The typical performance curves show the rejection with a capacitance of $2.2 \mu\text{Fd}$.)

Internal Voltage Programming

The LM0075 provides various precision output voltages simply by using one or more of the internal resistors. A particular voltage may be obtained by external connections as shown in Table I.

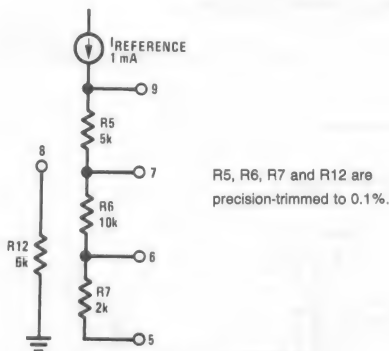

FIGURE 1

External Voltage Programming

An external resistance can be connected between pin 9 and ground to obtain any voltage from 0 to 27V using the following equation:

$$R_{EXT} = \frac{V_{OUT \text{ Desired}}}{1 \text{ mA}}$$

The reference current (I_{REF}) has a typical temperature coefficient of $-65 \text{ ppm}/^\circ\text{C}$. Choosing a resistive material with a temperature coefficient of $65 \text{ ppm}/^\circ\text{C}$ will compensate the negative temperature coefficient, resulting in an output voltage with minimal change over the operating temperature range. Example of a good resistive material is Nichrome, which has a typical temperature coefficient of $80 \text{ ppm}/^\circ\text{C}$.

12	Gnd		—	—	—
15		Gnd			
18	—		—	—	—

Since a current source is used as a reference, this makes remote voltage programming possible.

Current Limit Programming

The maximum current output of the device may be limited by adding two external resistors as shown below. The resistor values are easily calculated with the following equation:

$$I_{OUT(MAX)} = \left[\frac{R_{LIMIT}}{R_{SENSE}} + 1 \right] \times 100 \mu\text{A}$$

where $R_{SENSE} = 1$ to 10Ω

TL/H/5549-5

FIGURE 2. Current Limit Programming

This programmable current limit feature can be extended to make the LH0075 a programmable constant current source. This can be done by leaving pin 9 open and setting R_{LIMIT} and R_{SENSE} as desired.

For applications where the current limit is used, a minimum load current of $100 \mu\text{A}$ is established at the output. This arises from the fact that the constant current used in setting maximum output current is $100 \mu\text{A}$, and it goes directly to the output of the LH0075. If the total current drawn from the output is less than the minimum, the output will rise.

As in the remote voltage adjustment application, remote current sensing can be applied similarly. R_{SENSE} must be placed as close to the output of the LH0075 as possible, but R_{LIMIT} can be a fixed resistor or potentiometer located remotely from the device.

LH0076 Negative Precision Programmable Regulator

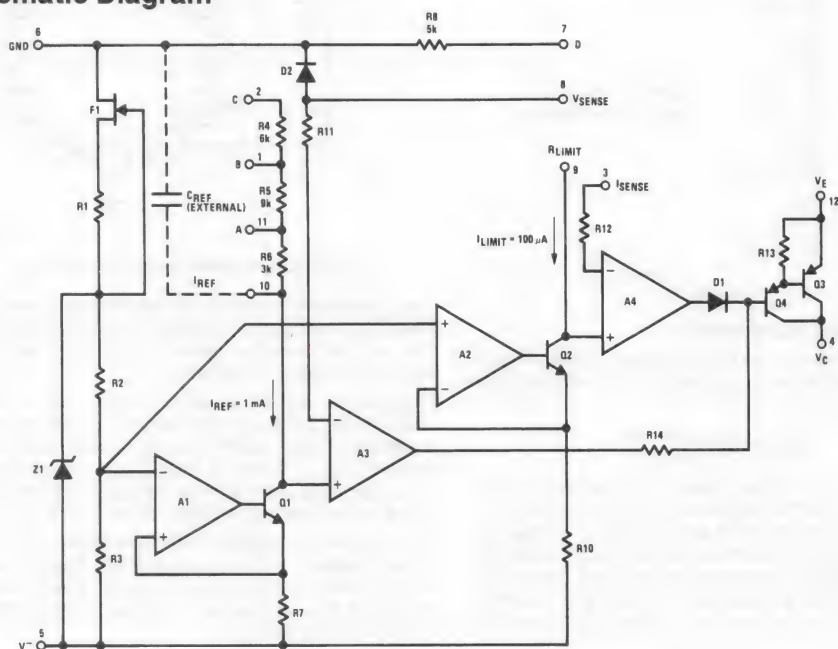

General Description

The LH0076 is a precision programmable regulator for negative voltages. Regulated output voltages from 0 to -27V may be obtained by using 1 external resistor. Also available without any external components are several fixed regulated voltages with accuracies to 0.1% (-3V, -5V, -6V, -8V, -9V, -12V, -15V and -18V). The output current limit is adjustable from 0 to 200 mA using 2 external resistors. These features provide an inventory of precision regulated values in 1 package.

Features

- Line regulation typically 0.005%/V
- Load regulation typically 0.02%
- Remote voltage sensing
- Ripple rejection—70 dB
- Output Adjustable to 0V
- Adjustable precision current limit
- Output current to 200 mA

*Recommended if device is far from filter capacitors

TL/H/5548-4

Application Information

The LH0076 does not require external capacitors for stable operation. However, an input bypass is recommended if the device is far from filter capacitors. A 0.1 μF for input bypassing should be adequate for most applications.

DESCRIPTION OF OPTIONS

External Voltage Programming

An external resistance can be connected between pin 10 and ground to obtain any voltage from 0 to -27V using the following equation:

$$R_{\text{EXT}} = \frac{V_{\text{OUT desired}}}{-1 \text{ mA}}$$

The reference current (I_{REF}) has a typical temperature coefficient of $-60 \text{ ppm}/^\circ\text{C}$. Choosing a resistive material with a temperature coefficient of $60 \text{ ppm}/^\circ\text{C}$ will compensate the negative tempco of the reference current, resulting in an output voltage with minimal change over the operating temperature range. Example of a good resistive material is nichrome, which has a typical tempco of $80 \text{ ppm}/^\circ\text{C}$. Nichrome is the resistive material used in the LH0076, resulting in output voltage drift of $20 \text{ ppm}/^\circ\text{C}$ typically.

Application Information (Continued)

Because a current source is used as a reference, remote voltage programming is possible.

Internal Voltage Programming

The LH0076 provides various precision output voltages simply by using 1 or more of the internal programming resistors. These voltages may be obtained by using the connections as shown in Table 1.

R_{TOTAL} is the total resistance between pin 10 and ground

R4, R5, R6 and R8 are precision trimmed to 0.1%

TL/H/5548-5

FIGURE 1

Current Limit Programming

The maximum current output of the device may be limited by adding 2 external resistors as shown in Figure 2. The resistor values are calculated using the following equation:

$$I_{OUT(MAX)} = \left[\frac{R_{LIMIT}}{R_{SENSE}} + 1 \right] \times 100\mu A$$

where $R_{SENSE} = 1$ to 10Ω

This programming current limit feature can be extended to make the LH0076 a programmable current sink. This can be done by leaving pin 10 open and setting R_{LIMIT} and R_{SENSE} as desired. (See Figure 3).

TL/H/5548-6

FIGURE 2. Current Limit Programming

For application where the current limit is used, a minimum load current of $100\mu A$ is established at the output. This arises from the fact that the constant current used in setting maximum output current is $100\mu A$, and it comes directly from the output of the LH0076. If the total current is less than this minimum current, the output will drop.

As in the remote voltage adjustment application, remote current sensing can be applied similarly. R_{SENSE} should be placed as close to the output of the LH0076 as possible, but R_{LIMIT} can be a resistor or potentiometer located remotely from the device.

LM104/LM204/LM304 Negative Regulator

General Description

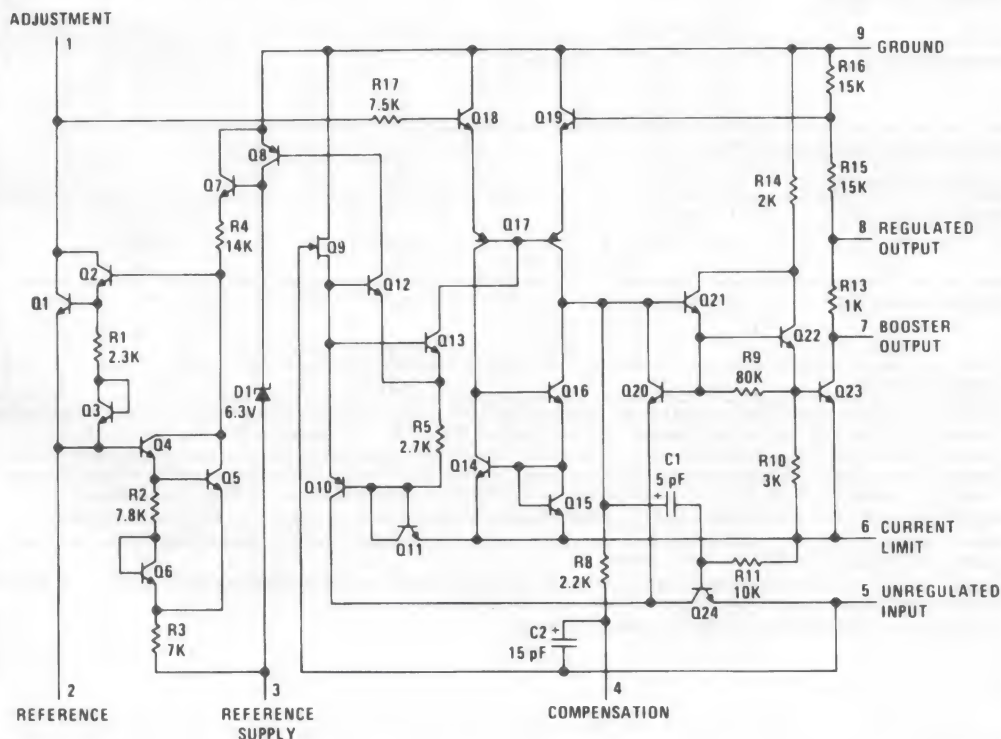

The LM104 series are precision voltage regulators which can be programmed by a single external resistor to supply any voltage from 40V down to zero while operating from a single unregulated supply. They can also provide 0.01-percent regulation in circuits using a separate, floating bias supply, where the output voltage is limited only by the breakdown of external pass transistors. Although designed primarily as linear, series regulators, the circuits can be used as switching regulators, current regulators or in a number of other control applications. Typical performance characteristics are:

- Subsurface zener reference
- 1 mV regulation no load to full load
- 0.01%/V line regulation
- 0.2 mV/V ripple rejection
- 0.3% temperature stability over military temperature range

The LM104 series is the complement of the LM105 positive regulator, intended for systems requiring regulated negative voltages which have a common ground with the unregulated supply. By themselves, they can deliver output currents to 25 mA, but external transistors can be added to get any desired current. The output voltage is set by external resistors, and either constant or foldback current limiting is made available.

The LM104 is specified for operation over the -55°C to $+125^{\circ}\text{C}$ military temperature range. The LM204 is specified for operation over the -25°C to $+85^{\circ}\text{C}$ temperature range. The LM304 is specified for operation from 0°C to $+70^{\circ}\text{C}$.

Note 1: The maximum junction temperature of the LM104 is 150°C, while that of the LM204 is 125°C and LM304 is 100°C. For operating at elevated temperatures, devices in the TO-5 package must be derated based on a thermal resistance of 150°C/W, junction to ambient, or 45°C/W, junction to case.

Note 2: These specifications apply for junction temperatures between –55°C and 150°C (between –25°C and 100°C for the LM204 and 0°C to +85°C for the LM304) and for input and output voltages within the ranges given, unless otherwise specified. The load and line regulation specifications are for constant junction temperature. Temperature drift effects must be taken into account separately when the unit is operating under conditions of high dissipation.

Note 3: When external booster transistors are used, the minimum output-input voltage differential is increased, in the worst case, by approximately 1V.

Note 4: The output currents given, as well as the load regulation, can be increased by the addition of external transistors. The improvement factor will be roughly equal to the composite current gain of the added transistors.

Note 5: With zero output, the dc line regulation is determined from the ripple rejection. Hence, with output voltages between 0V and –5V, a dc output variation, determined from the ripple rejection, must be added to find the worst-case line regulation.

Note 6: Refer to RETS104X drawing for military specifications for the LM104.

LM105/LM205/LM305/LM305A, LM376 Voltage Regulators

General Description

The LM105 series are positive voltage regulators similar to the LM100, except that an extra gain stage has been added for improved regulation. A redesign of the biasing circuitry removes any minimum load current requirement and at the same time reduces standby current drain, permitting higher voltage operation. They are direct, plug-in replacements for the LM100 in both linear and switching regulator circuits with output voltages greater than 4.5V. Important characteristics of the circuits are:

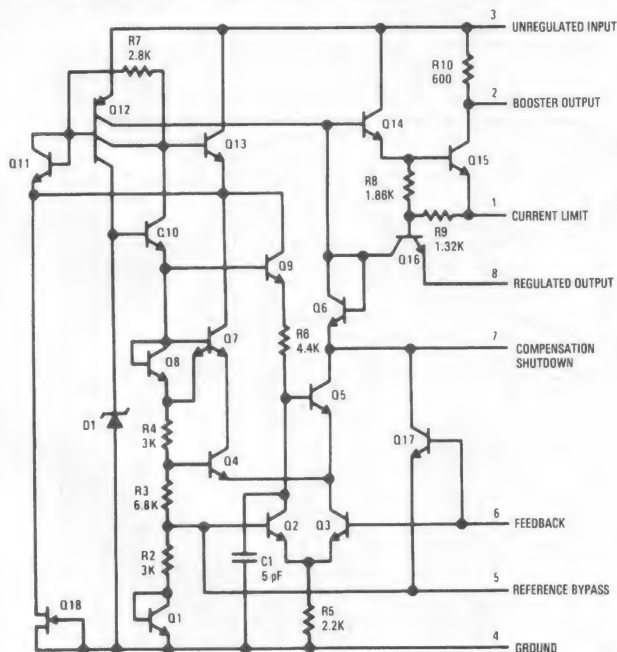

- Output voltage adjustable from 4.5V to 40V
- Output currents in excess of 10A possible by adding external transistors
- Load regulation better than 0.1%, full load with current limiting

- DC line regulation guaranteed at 0.03%/V
- Ripple rejection on 0.01%V
- 45 mA output current without external pass transistor (LM305A)

Like the LM100, they also feature fast response to both load and line transients, freedom from oscillations with varying resistive and reactive loads and the ability to start reliably on any load within rating. The circuits are built on a single silicon chip and are supplied in either an 8-lead, TO-5 header or a 1/4" x 1/4" metal flat package.

The LM105 is specified for operation for $-55^{\circ}\text{C} \leq T_A \leq +125^{\circ}\text{C}$, the LM205 is specified for $-25^{\circ}\text{C} \leq T_A \leq +85^{\circ}\text{C}$, and the LM305/LM305A, LM376 is specified for $0^{\circ}\text{C} \leq T_A \leq +70^{\circ}\text{C}$.

Note 1: The maximum junction temperature of the LM105 and LM305A is 150°C, the LM205 and LM376 is 100°C, and the LM305 is 85°C. For operation at elevated temperatures, devices in the TO-5 package must be derated based on a thermal resistance of 231°C/W junction to ambient, or 25°C/W junction to case. For the epoxy dual-in-line packages, derating is based on a thermal resistance of 138°C/W junction to ambient. Peak dissipations to 1W are allowable providing the dissipation rating is not exceeded with the power average over a five second interval for the LM105 and LM205, and averaged over a two second interval for the LM305.

Note 2: Unless otherwise specified, these specifications apply for temperatures within the operating temperature range, for input and output voltages within the range given, and for a divider impedance seen by the feedback terminal of 2 kΩ. Load and line regulation specifications are for a constant junction temperature. Temperature drift effects must be taken into account separately when the unit is operating under conditions of high dissipation.

Note 3: The output currents given, as well as the load regulation, can be increased by the addition of external transistors. The improvement factor will be roughly equal to the composite current gain of the added transistors.

Note 4: With no external pass transistor.

Note 5: Refer to RETS105X Drawing for military specifications for the LM105.

LM109/LM309 5-Volt Regulator

General Description

The LM109 series are complete 5V regulators fabricated on a single silicon chip. They are designed for local regulation on digital logic cards, eliminating the distribution problems associated with single-point regulation. The devices are available in two standard transistor packages. In the solid-kovar TO-5 header, it can deliver output currents in excess of 200 mA, if adequate heat sinking is provided. With the TO-3 power package, the available output current is greater than 1A.

The regulators are essentially blowout proof. Current limiting is included to limit the peak output current to a safe value. In addition, thermal shutdown is provided to keep the IC from overheating. If internal dissipation becomes too great, the regulator will shut down to prevent excessive heating.

Considerable effort was expended to make these devices easy to use and to minimize the number of external components. It is not necessary to bypass the output, although this does improve transient response somewhat. Input bypassing is needed, however, if the regulator is located very

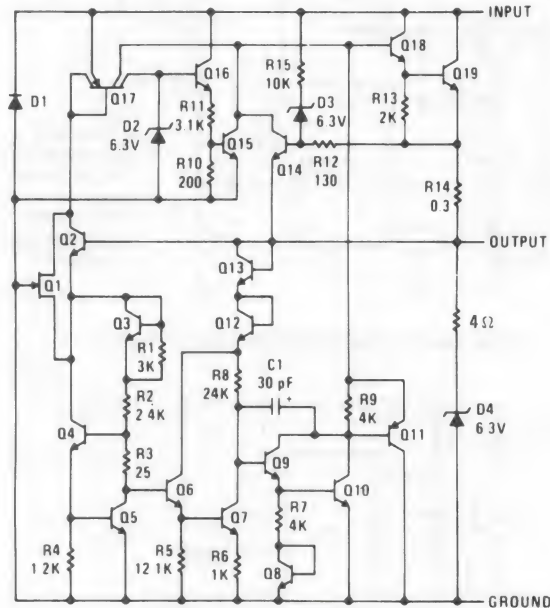

far from the filter capacitor of the power supply. Stability is also achieved by methods that provide very good rejection of load or line transients as are usually seen with TTL logic.

Although designed primarily as a fixed-voltage regulator, the output of the LM109 series can be set to voltages above 5V, as shown. It is also possible to use the circuits as the control element in precision regulators, taking advantage of the good current-handling capability and the thermal overload protection.

Features

- Specified to be compatible, worst case, with TTL and DTL
- Output current in excess of 1A
- Internal thermal overload protection
- No external components required

Application Hints

- Bypass the input** of the LM109 to ground with $\geq 0.2 \mu\text{F}$ ceramic or solid tantalum capacitor if main filter capacitor is more than 4 inches away.
- Use steel package** instead of aluminum if more than 5,000 thermal cycles are expected. ($\Delta T \geq 50^\circ\text{C}$)
- Avoid insertion of regulator into "live" socket** if input voltage is greater than 10V. The output will rise to within 2V of the unregulated input if the ground pin does not make contact, possibly damaging the load. The LM109 may also be damaged if a large output capacitor is charged up, then discharged through the internal clamp zener when the ground pin makes contact.
- The output clamp zener** is designed to absorb transients only. It will not clamp the output effectively if a failure occurs in the internal power transistor structure. Zener dynamic impedance is $\approx 4\Omega$. Continuous RMS current into the zener should not exceed 0.5A.
- Paralleling of LM109s** for higher output current is not recommended. Current sharing will be almost nonexistent, leading to a current limit mode operation for devices with the highest initial output voltage. The current limit devices may also heat up to the thermal shutdown point ($\approx 175^\circ\text{C}$). Long term reliability cannot be guaranteed under these conditions.

f. Preventing latchoff for loads connected to negative voltage:

If the output of the LM109 is pulled negative by a high current supply so that the output pin is more than 0.5V negative with respect to the ground pin, the LM109 can latch off. This can be prevented by clamping the ground pin to the output pin with a germanium or Schottky diode as shown. A silicon diode (1N4001) at the output is also needed to keep the positive output from being pulled too far negative. The 10Ω resistor will raise $+V_{\text{OUT}}$ by $\approx 0.05\text{V}$.

*Determines output current. If wirewound resistor is used, bypass with 0.1 μF.

LM117/LM317 3-Terminal Adjustable Regulator

General Description

The LM117/LM317 are adjustable 3-terminal positive voltage regulators capable of supplying in excess of 1.5A over a 1.2V to 37V output range. They are exceptionally easy to use and require only two external resistors to set the output voltage. Further, both line and load regulation are better than standard fixed regulators. Also, the LM117 is packaged in standard transistor packages which are easily mounted and handled.

In addition to higher performance than fixed regulators, the LM117 series offers full overload protection available only in IC's. Included on the chip are current limit, thermal overload protection and safe area protection. All overload protection circuitry remains fully functional even if the adjustment terminal is disconnected.

Normally, no capacitors are needed unless the device is situated more than 6 inches from the input filter capacitors in which case an input bypass is needed. An optional output capacitor can be added to improve transient response. The adjustment terminal can be bypassed to achieve very high ripple rejections ratios which are difficult to achieve with standard 3-terminal regulators.

Besides replacing fixed regulators, the LM117 is useful in a wide variety of other applications. Since the regulator is "floating" and sees only the input-to-output differential voltage, supplies of several hundred volts can be regulated as long as the maximum input to output differential is not exceeded, i.e., avoid short-circuiting the output.

Also, it makes an especially simple adjustable switching regulator, a programmable output regulator, or by connecting a fixed resistor between the adjustment pin and output, the LM117 can be used as a precision current regulator. Supplies with electronic shutdown can be achieved by clamping the adjustment terminal to ground which programs the output to 1.2V where most loads draw little current.

The LM117K and LM317K are packaged in standard TO-3 transistor packages while the LM117H and LM317H are packaged in a solid Kovar base TO-39 transistor package. The LM117 is rated for operation from -55°C to $+150^{\circ}\text{C}$, and the LM317 from 0°C to $+125^{\circ}\text{C}$. The LM317T and LM317MP, rated for operation over a 0°C to $+125^{\circ}\text{C}$ range, are available in a TO-220 plastic package and a TO-202 package, respectively.

For applications requiring greater output current in excess of 3A and 5A, see LM150 series and LM138 series data sheets, respectively. For the negative complement, see LM137 series data sheet.

LM117 Series Packages and Power Capability

Device	Package	Rated Power Dissipation	Design Load Current
LM117	TO-3	20W	1.5A
LM317	TO-39	2W	0.5A
LM317T	TO-220	15W	1.5A
LM317M	TO-202	7.5W	0.5A

Features

- Adjustable output down to 1.2V
- Guaranteed 1.5A output current
- Line regulation typically 0.01%/V
- Load regulation typically 0.1%
- Current limit constant with temperature
- 100% electrical burn-in
- Eliminates the need to stock many voltages
- Standard 3-lead transistor package
- 80 dB ripple rejection
- Output is short-circuit protected

Typical Applications

1.2V–25V Adjustable Regulator

TL/H/9063-1

Full output current not available at high input-output voltages

*Needed if device is more than 6 inches from filter capacitors.

†Optional—improves transient response. Output capacitors in the range of 1 μF to 1000 μF of aluminum or tantalum electrolytic are commonly used to provide improved output impedance and rejection of transients.

$$\dagger V_{OUT} = 1.25V \left(1 + \frac{R2}{R1} \right) + I_{ADJ}(R2)$$

Digitally Selected Outputs

*Sets maximum V_{OUT}

Output Capacitor = 0 unless otherwise noted

TL/H/9063-4

Application Hints

In operation, the LM117 develops a nominal 1.25V reference voltage, V_{REF} , between the output and adjustment terminal. The reference voltage is impressed across program resistor R_1 and, since the voltage is constant, a constant current I_1 then flows through the output set resistor R_2 , giving an output voltage of

$$V_{OUT} = V_{REF} \left(1 + \frac{R_2}{R_1} \right) + I_{ADJ} R_2$$

FIGURE 1

TL/H/9063-5

Since the 100 μ A current from the adjustment terminal represents an error term, the LM117 was designed to minimize I_{ADJ} and make it very constant with line and load changes. To do this, all quiescent operating current is returned to the output establishing a minimum load current requirement. If there is insufficient load on the output, the output will rise.

External Capacitors

An input bypass capacitor is recommended. A 0.1 μ F disc or 1 μ F solid tantalum on the input is suitable input bypassing for almost all applications. The device is more sensitive to the absence of input bypassing when adjustment or output capacitors are used but the above values will eliminate the possibility of problems.

The adjustment terminal can be bypassed to ground on the LM117 to improve ripple rejection. This bypass capacitor prevents ripple from being amplified as the output voltage is increased. With a 10 μ F bypass capacitor 80 dB ripple rejection is obtainable at any output level. Increases over 10 μ F do not appreciably improve the ripple rejection at frequencies above 120 Hz. If the bypass capacitor is used, it is sometimes necessary to include protection diodes to prevent the capacitor from discharging through internal low current paths and damaging the device.

In general, the best type of capacitors to use is solid tantalum. Solid tantalum capacitors have low impedance even at high frequencies. Depending upon capacitor construction, it takes about 25 μ F in aluminum electrolytic to equal 1 μ F solid tantalum at high frequencies. Ceramic capacitors are also good at high frequencies; but some types have a large decrease in capacitance at frequencies around 0.5 MHz. For this reason, 0.01 μ F disc may seem to work better than a 0.1 μ F disc as a bypass.

Although the LM117 is stable with no output capacitors, like any feedback circuit, certain values of external capacitance can cause excessive ringing. This occurs with values be-

tween 500 pF and 5000 pF. A 1 μ F solid tantalum (or 25 μ F aluminum electrolytic) on the output swamps this effect and insures stability. Any increase of the load capacitance larger than 10 μ F will merely improve the loop stability and output impedance.

Load Regulation

The LM117 is capable of providing extremely good load regulation but a few precautions are needed to obtain maximum performance. The current set resistor connected between the adjustment terminal and the output terminal (usually 240 Ω) should be tied directly to the output (case) of the regulator rather than near the load. This eliminates line drops from appearing effectively in series with the reference and degrading regulation. For example, a 15V regulator with 0.05 Ω resistance between the regulator and load will have a load regulation due to line resistance of $0.05\Omega \times I_L$. If the set resistor is connected near the load the effective line resistance will be $0.05\Omega (1 + R_2/R_1)$ or in this case, 11.5 times worse.

Figure 2 shows the effect of resistance between the regulator and 240 Ω set resistor.

TL/H/9063-6

FIGURE 2. Regulator with Line Resistance in Output Lead

With the TO-3 package, it is easy to minimize the resistance from the case to the set resistor, by using two separate leads to the case. However, with the TO-5 package, care should be taken to minimize the wire length of the output lead. The ground of R_2 can be returned near the ground of the load to provide remote ground sensing and improve load regulation.

Protection Diodes

When external capacitors are used with any IC regulator it is sometimes necessary to add protection diodes to prevent the capacitors from discharging through low current points into the regulator. Most 10 μ F capacitors have low enough internal series resistance to deliver 20A spikes when shorted. Although the surge is short, there is enough energy to damage parts of the IC.

When an output capacitor is connected to a regulator and the input is shorted, the output capacitor will discharge into the output of the regulator. The discharge current depends on the value of the capacitor, the output voltage of the regulator, and the rate of decrease of V_{IN} . In the LM117, this discharge path is through a large junction that is able to sustain 15A surge with no problem. This is not true of other types of positive regulators. For output capacitors of 25 μ F or less, there is no need to use diodes.

Application Hints (Continued)

The bypass capacitor on the adjustment terminal can discharge through a low current junction. Discharge occurs when *either* the input or output is shorted. Internal to the LM117 is a 50Ω resistor which limits the peak discharge

current. No protection is needed for output voltages of 25V or less and 10 μF capacitance. *Figure 3* shows an LM117 with protection diodes included for use with outputs greater than 25V and high values of output capacitance.

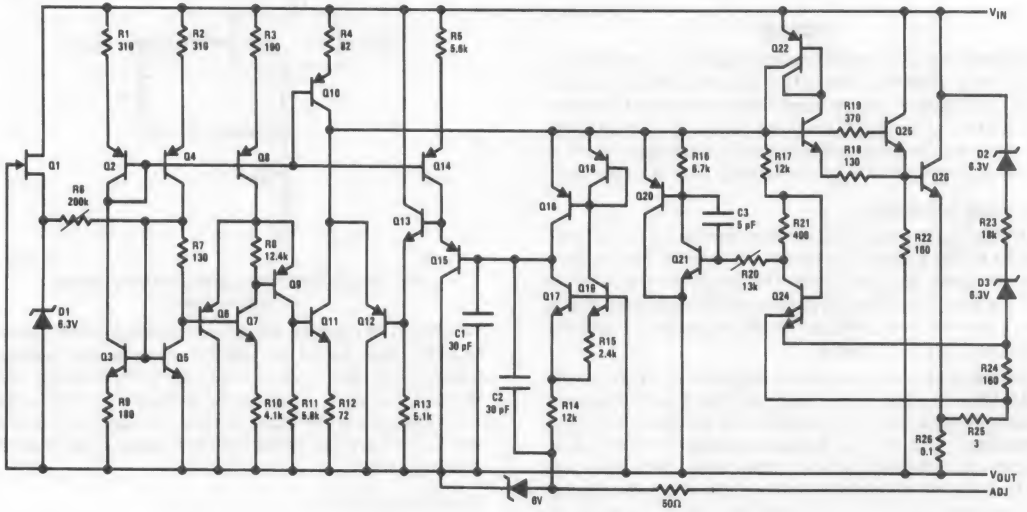

$$V_{OUT} = 1.25V \left(1 + \frac{R_2}{R_1} \right) + I_{ADJ}R_2$$

LM117HV/LM317HV 3-Terminal Adjustable Regulator

General Description

The LM117HV/LM317HV are adjustable 3-terminal positive voltage regulators capable of supplying in excess of 1.5A over a 1.2V to 57V output range. They are exceptionally easy to use and require only two external resistors to set the output voltage. Further, both line and load regulation are better than standard fixed regulators. Also, the LM117HV is packaged in standard transistor packages which are easily mounted and handled.

In addition to higher performance than fixed regulators, the LM117HV series offers full overload protection available only in IC's. Included on the chip are current limit, thermal overload protection and safe area protection. All overload protection circuitry remains fully functional even if the adjustment terminal is disconnected.

Normally, no capacitors are needed unless the device is situated more than 6 inches from the input filter capacitors in which case an input bypass is needed. An optional output capacitor can be added to improve transient response. The adjustment terminal can be bypassed to achieve very high ripple rejections ratios which are difficult to achieve with standard 3-terminal regulators.

Besides replacing fixed regulators, the LM117HV is useful in a wide variety of other applications. Since the regulator is "floating" and sees only the input-to-output differential voltage, supplies of several hundred volts can be regulated as long as the maximum input to output differential is not exceeded, i.e. do not short the output to ground.

Also, it makes an especially simple adjustable switching regulator, a programmable output regulator, or by connecting a fixed resistor between the adjustment and output, the LM117HV can be used as a precision current regulator. Supplies with electronic shutdown can be achieved by clamping the adjustment terminal to ground which programs the output to 1.2V where most loads draw little current.

The LM117HVK STEEL, and LM317HVK STEEL are packaged in standard TO-3 transistor packages while the LM117HVH, and LM317HVH are packaged in a solid Kovar base TO-39 transistor package. The LM117HV is rated for operation from -55°C to $+150^{\circ}\text{C}$, and the LM317HV from 0°C to $+125^{\circ}\text{C}$.

Features

- Adjustable output down to 1.2V
- Guaranteed 1.5A output current
- Line regulation typically 0.01%/V
- Load regulation typically 0.1%
- Current limit constant with temperature
- 100% electrical burn-in
- Eliminates the need to stock many voltages
- Standard 3-lead transistor package
- 80 dB ripple rejection
- Output is short-circuit protected

Typical Applications

1.2V–45V Adjustable Regulator

Full output current not available at high input-output voltages

†Optional—improves transient response. Output capacitors in the range of 1 μF to 1000 μF of aluminum or tantalum electrolytic are commonly used to provide improved output impedance and rejection of transients.

*Needed if device is more than 6 inches from filter capacitors.

$$\dagger V_{\text{OUT}} = 1.25V \left(1 + \frac{R_2}{R_1} \right) + I_{\text{ADJ}} R_2$$

Digitally Selected Outputs

*Sets maximum V_{OUT}

5V Logic Regulator with Electronic Shutdown*

*Min. output $\approx 1.2V$

Application Hints

In operation, the LM117HV develops a nominal 1.25V reference voltage, V_{REF} , between the output and adjustment terminal. The reference voltage is impressed across program resistor R_1 and, since the voltage is constant, a constant current I_1 then flows through the output set resistor R_2 , giving an output voltage of

$$V_{OUT} = V_{REF} \left(1 + \frac{R_2}{R_1} \right) + I_{ADJ} R_2$$

TL/H/9062-5

FIGURE 1

Since the 100 μ A current from the adjustment terminal represents an error term, the LM117HV was designed to minimize I_{ADJ} and make it very constant with line and load changes. To do this, all quiescent operating current is returned to the output establishing a minimum load current requirement. If there is insufficient load on the output, the output will rise.

External Capacitors

An input bypass capacitor is recommended. A 0.1 μ F disc or 1 μ F solid tantalum on the input is suitable input bypassing for almost all applications. The device is more sensitive to the absence of input bypassing when adjustment or output capacitors are used but the above values will eliminate the possibility of problems.

The adjustment terminal can be bypassed to ground on the LM117HV to improve ripple rejection. This bypass capacitor prevents ripple from being amplified as the output voltage is increased. With a 10 μ F bypass capacitor 80 dB ripple rejection is obtainable at any output level. Increases over 10 μ F do not appreciably improve the ripple rejection at frequencies above 120 Hz. If the bypass capacitor is used, it is sometimes necessary to include protection diodes to prevent the capacitor from discharging through internal low current paths and damaging the device.

In general, the best type of capacitors to use are solid tantalum. Solid tantalum capacitors have low impedance even at high frequencies. Depending upon capacitor construction, it takes about 25 μ F in aluminum electrolytic to equal 1 μ F solid tantalum at high frequencies. Ceramic capacitors are also good at high frequencies; but some types have a large decrease in capacitance at frequencies around 0.5 MHz. For this reason, 0.01 μ F disc may seem to work better than a 0.1 μ F disc as a bypass.

Although the LM117HV is stable with no output capacitors, like any feedback circuit, certain values of external capaci-

tance can cause excessive ringing. This occurs with values between 500 pF and 5000 pF. A 1 μ F solid tantalum (or 25 μ F aluminum electrolytic) on the output swamps this effect and insures stability. Any increase of load capacitance larger than 10 μ F will merely improve the loop stability and output impedance.

Load Regulation

The LM117HV is capable of providing extremely good load regulation but a few precautions are needed to obtain maximum performance. The current set resistor connected between the adjustment terminal and the output terminal (usually 240 Ω) should be tied directly to the output of the regulator rather than near the load. This eliminates line drops from appearing effectively in series with the reference and degrading regulation. For example, a 15V regulator with 0.05 Ω resistance between the regulator and load will have a load regulation due to line resistance of $0.05\Omega \times I_L$. If the set resistor is connected near the load the effective line resistance will be $0.05\Omega (1 + R_2/R_1)$ or in this case, 11.5 times worse.

Figure 2 shows the effect of resistance between the regulator and 240 Ω set resistor.

TL/H/9062-6

FIGURE 2. Regulator with Line Resistance in Output Lead

With the TO-3 package, it is easy to minimize the resistance from the case to the set resistor, by using two separate leads to the case. However, with the TO-5 package, care should be taken to minimize the wire length of the output lead. The ground of R_2 can be returned near the ground of the load to provide remote ground sensing and improve load regulation.

Protection Diodes

When external capacitors are used with any IC regulator it is sometimes necessary to add protection diodes to prevent the capacitors from discharging through low current points into the regulator. Most 10 μ F capacitors have low enough internal series resistance to deliver 20A spikes when shorted. Although the surge is short, there is enough energy to damage parts of the IC.

When an output capacitor is connected to a regulator and the input is shorted, the output capacitor will discharge into the output of the regulator. The discharge current depends on the value of the capacitor, the output voltage of the regulator, and the rate of decrease of V_{IN} . In the LM117HV, this discharge path is through a large junction that is able to sustain 15A surge with no problem. This is not true of other types of positive regulators. For output capacitors of 25 μ F or less, there is no need to use diodes.

The bypass capacitor on the adjustment terminal can discharge through a low current junction. Discharge occurs when *either* the input or output is shorted. Internal to the LM117HV is a 50Ω resistor which limits the peak discharge current. No protection is needed for output voltages of 25V or less and 10 μF capacitance. Figure 3 shows an LM117HV with protection diodes included for use with outputs greater than 25V and high values of output capacitance.

LM120/LM320 Series 3-Terminal Negative Regulators

General Description

The LM120 series are three-terminal negative regulators with a fixed output voltage of $-5V$, $-12V$, and $-15V$, and up to $1.5A$ load current capability. Where other voltages are required, the LM137 series provides an output voltage range of $-1.2V$ to $-4.7V$.

The LM120 need only one external component—a compensation capacitor at the output, making them easy to apply. Worst case guarantees on output voltage deviation due to any combination of line, load or temperature variation assure satisfactory system operation.

Exceptional effort has been made to make the LM120 Series immune to overload conditions. The regulators have current limiting which is independent of temperature, combined with thermal overload protection. Internal current limiting protects against momentary faults while thermal shutdown prevents junction temperatures from exceeding safe limits during prolonged overloads.

Although primarily intended for fixed output voltage applications, the LM120 Series may be programmed for higher output voltages with a simple resistive divider. The low quiescent drain current of the devices allows this technique to be used with good regulation.

Features

- Preset output voltage error less than $\pm 3\%$
- Preset current limit
- Internal thermal shutdown
- Operates with input-output voltage differential down to $1V$
- Excellent ripple rejection
- Low temperature drift
- Easily adjustable to higher output voltage

LM120 Series Packages and Power Capability

Device	Package	Rated Power Dissipation	Design Load Current
LM120	TO-3	20W	1.5A
LM320	TO-39	2W	0.5A
LM320T	TO-220	15W	1.5A
LM320M	TO-202	7.5W	0.5A

Typical Applications

Preventing Positive Regulator Latch-Up

TL/H/7767-1

R1 & D1 allow the positive regulator to "start-up" when $+V_{IN}$ is delayed relative to $-V_{IN}$ and a heavy load is drawn between the outputs. Without R1 & D1, most three-terminal regulators will not start with heavy (0.1A–1A) load current flowing to the negative regulator, even though the positive output is clamped by D2.

*R2 is optional. Ground pin current from the positive regulator flowing through R1 will increase $+V_{OUT} \approx 60 \text{ mV}$ if R2 is omitted.

Fixed Regulator

TL/H/7767-2

*Required if regulator is separated from filter capacitor by more than $3"$. For value given, capacitor must be solid tantalum. $25 \mu F$ aluminum electrolytic may be substituted.

†Required for stability. For value given, capacitor must be solid tantalum. $25 \mu F$ aluminum electrolytic may be substituted. Values given may be increased without limit.

For output capacitance in excess of $100 \mu F$, a high current diode from input to output (1N4001, etc.) will protect the regulator from momentary input shorts.

LM123/LM323 3 Amp, 5 Volt Positive Regulator

General Description

The LM123 is a three-terminal positive regulator with a pre-set 5V output and a load driving capability of 3 amps. New circuit design and processing techniques are used to provide the high output current without sacrificing the regulation characteristics of lower current devices.

The 3 amp regulator is virtually blowout proof. Current limiting, power limiting, and thermal shutdown provide the same high level of reliability obtained with these techniques in the LM109 1 amp regulator.

No external components are required for operation of the LM123. If the device is more than 4 inches from the filter capacitor, however, a $1\ \mu\text{F}$ solid tantalum capacitor should be used on the input. A $0.1\ \mu\text{F}$ or larger capacitor may be used on the output to reduce load transient spikes created by fast switching digital logic, or to swamp out stray load capacitance.

An overall worst case specification for the combined effects of input voltage, load currents, ambient temperature, and

power dissipation ensure that the LM123 will perform satisfactorily as a system element.

For applications requiring other voltages, see LM150 series data sheet.

Operation is guaranteed over the junction temperature range -55°C to $+150^{\circ}\text{C}$. An electrically identical LM323 is specified from 0°C to $+125^{\circ}\text{C}$ junction temperature. A hermetic TO-3 package is used for high reliability and low thermal resistance.

Features

- 3 amp output current
- Internal current and thermal limiting
- $0.01\ \Omega$ typical output impedance
- 7.5V minimum input voltage
- 30W power dissipation
- 100% electrical burn-in

Long Term Stability				35			35	mW
Thermal Resistance Junction to Case (Note 2)			2			2		$^\circ\text{C/W}$

Note 1: Unless otherwise noted, specifications apply for $-55^\circ\text{C} \leq T_J \leq +150^\circ\text{C}$ for the LM123 and $0^\circ\text{C} \leq T_J \leq +125^\circ\text{C}$ for the LM323. Although power dissipation is internally limited, specifications apply only for $P \leq 30\text{W}$.

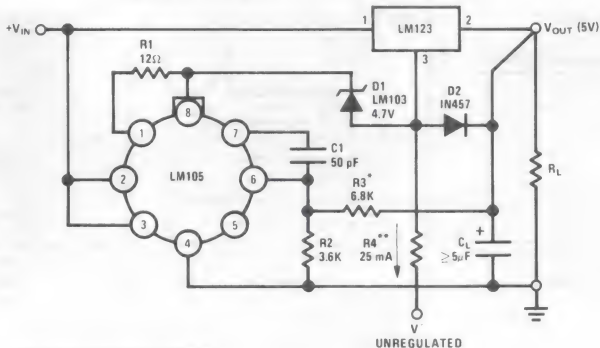

Note 2: Without a heat sink, the thermal resistance of the TO-3 package is about 35°C/W . With a heat sink, the effective thermal resistance can only approach the specified values of 2°C/W , depending on the efficiency of the heat sink.

Note 3: Load and line regulation are specified at constant junction temperature. Pulse testing is required with a pulse width $\leq 1\text{ ms}$ and a duty cycle $\leq 5\%$.

Note 4: Refer to RETS123K drawing for military specifications for the LM123K.

LM125/LM325/LM325A, LM126/LM326 Voltage Regulators

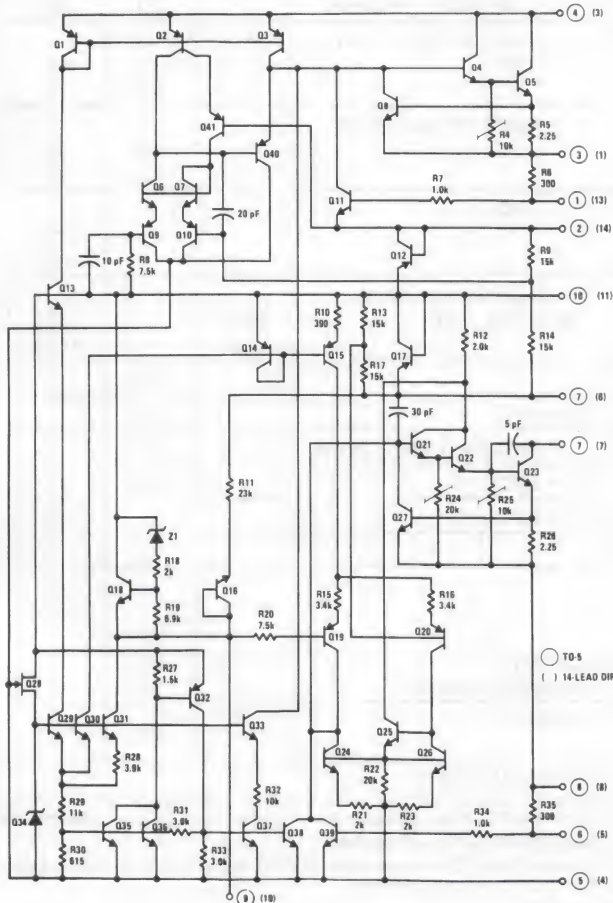

General Description

These are dual polarity tracking regulators designed to provide balanced positive and negative output voltages at current up to 100 mA, the devices are set for $\pm 15\text{V}$ and $\pm 12\text{V}$ outputs respectively. Input voltages up to $\pm 30\text{V}$ can be used and there is provision for adjustable current limiting. These devices are available in three package types to accommodate various power requirements and temperature ranges.

Features

- $\pm 15\text{V}$ and $\pm 12\text{V}$ tracking outputs
- Output current to 100 mA
- Output voltage balanced to within 1% (LM125, LM126, LM325A)
- Line and load regulation of 0.06%
- Internal thermal overload protection
- Standby current drain of 3 mA
- Externally adjustable current limit
- Internal current limit

TL/H/7776-9

The circuit diagram illustrates a 10-bit DAC implemented with discrete components. The input signals are V_{IL} and V_{IH} , which define the logic levels: $V_{IH} \approx 2.0V$ and $V_{IL} \leq 0.8V$. These inputs drive a network of 1N914 diodes and resistors (200Ω). The output of this network is connected to the base of a 2N2222 transistor. The emitter of the 2N2222 is grounded through a 100Ω resistor, and its collector is connected to the base of a 2N3019 transistor. The 2N3019's emitter is also grounded through a 100Ω resistor, and its collector is connected to the positive input (+VIN) of a 10-bit digital-to-analog converter (DAC) IC. The DAC IC has 10 pins labeled 1 through 10. Pin 1 is connected to ground, pin 10 is connected to +VIN, and pin 7 is connected to -VIN. The output of the DAC is taken from pin 6, which is connected to the output terminal -VOUT. A feedback capacitor C4** is connected between -VOUT and -VIN. The DAC IC also includes two internal capacitors, C1† and C2†, each valued at 1μF, connected to pins 4 and 5 respectively. The power supply rails are +VIN and -VIN.

†Solid tantalum

††Short pins 6 and 7 on dip

*Required if regulator is located an appreciable distance from power supply filter.

****Although no capacitor is needed for stability, it does help transient response. (If needed use 1 μ F electrolytic).**

LM133/LM333 3-Ampere Adjustable Negative Regulators

General Description

The LM133/LM333 are adjustable 3-terminal negative voltage regulators capable of supplying in excess of $-3.0A$ over an output voltage range of $-1.2V$ to $-32V$. These regulators are exceptionally easy to apply, requiring only 2 external resistors to set the output voltage and 1 output capacitor for frequency compensation. The circuit design has been optimized for excellent regulation and low thermal transients. Further, the LM133 series features internal current limiting, thermal shutdown and safe-area compensation, making them virtually blowout-proof against overloads. The LM133/LM333 serve a wide variety of applications including local on-card regulation, programmable-output voltage regulation or precision current regulation. The LM133/LM333 are ideal complements to the LM150/LM350 adjustable positive regulators.

Features

- Output voltage adjustable from $-1.2V$ to $-32V$
- $3.0A$ output current guaranteed, $-55^{\circ}C$ to $+150^{\circ}C$
- Line regulation typically $0.01\%/V$
- Load regulation typically 0.1%
- Excellent rejection of thermal transients
- $50\text{ ppm}/^{\circ}C$ temperature coefficient
- Temperature-independent current limit
- Internal thermal overload protection
- 100% electrical burn-in
- Standard 3-lead transistor package
- Output is short circuit protected

Typical Applications

Adjustable Negative Voltage Regulator

TL/H/9065-3

Full output current not available at high input-output voltages.

$$-V_{OUT} = -1.25V \left(1 + \frac{R2}{120\Omega} \right) + (-I_{ADJ} \times R2)$$

[†]C1 = $1\text{ }\mu F$ solid tantalum or $10\text{ }\mu F$ aluminum electrolytic required for stability.

^{*}C2 = $1\text{ }\mu F$ solid tantalum is required only if regulator is more than 4" from power supply filter capacitor.

Output capacitors in the range of $1\text{ }\mu F$ to $1000\text{ }\mu F$ of aluminum or tantalum electrolytic are commonly used to provide improved output impedance and rejection of transients.

Thermal Resistance Junction to Ambient (No Heatsink)	K Package T Package	35 50			$^\circ\text{C}/\text{W}$ $^\circ\text{C}/\text{W}$	

Note 1: Unless otherwise specified, these specifications apply: $-55^\circ\text{C} \leq T_J \leq +150^\circ\text{C}$ for the LM133; and $-40^\circ\text{C} \leq T_J \leq +125^\circ\text{C}$ for the LM333; $|V_{\text{IN}} - V_{\text{OUT}}| = 5\text{V}$; and $I_{\text{OUT}} = 0.5\text{A}$. Although power dissipation is internally limited, these specifications are applicable for power dissipations up to 30W .

Note 2: Regulation is measured at constant junction temperature, using pulse testing with a low duty cycle. Changes in output voltage due to heating effects are covered under the specification for thermal regulation. Load regulation is measured on the output pin at a point $1/8"$ below the base of the TO-3 package.

Note 3: Testing limits are guaranteed and 100% tested in production.

Note 4: Design limits are guaranteed (but not 100% production tested) over the indicated temperature and supply voltage ranges. These limits are not used to calculate outgoing quality levels.

Note 5: Specifications in **boldface** apply over the full rated temperature range.

Note 6: The output capability of the LM333 is guaranteed at 3A in the range of $3\text{V} \leq |V_{\text{IN}} - V_{\text{OUT}}| \leq 10\text{V}$. At voltages above 10V , the available output current decreases, but in the range $10\text{V} \leq |V_{\text{IN}} - V_{\text{OUT}}| \leq 15\text{V}$, the available current is $30\text{W} - |V_{\text{IN}} - V_{\text{OUT}}|$. At voltages higher than 15V , refer to graphs for actual guaranteed output current available.

THERMAL REGULATION

When power is dissipated in an IC, a temperature gradient occurs across the IC chip affecting the individual IC circuit components. With an IC regulator, this gradient can be especially severe since the power dissipation is large. Thermal regulation is the effect of these temperature gradients on output voltage (in percentage output change) per watt of power change in a specified time. Thermal regulation error is independent of electrical regulation or temperature coefficient, and occurs within 5 ms to 50 ms after a change in power dissipation. Thermal regulation depends on IC layout as well as electrical design. The thermal regulation of a voltage regulator is defined as the percentage change of V_{OUT} ,

per watt, within the first 10 ms after a step of power is applied. The LM133's specification is 0.01%/W, max.

In *Figure 1*, a typical LM133's output drifts only 2 mV (or 0.02% of $V_{OUT} = -10V$) when a 20W pulse is applied for 10 ms. This performance is thus well inside the specification limit of $0.01\%/W \times 20W = 0.2\%$ max. When the 20W pulse is ended, the thermal regulation again shows a 2 mV step as the LM133 chip cools off. Note that the load regulation error of about 1 mV (0.01%) is additional to the thermal regulation error. In *Figure 2*, when the 20W pulse is applied for 100 ms, the output drifts only slightly beyond the drift in the first 10 ms, and the thermal error stays well within 0.1% (10 mV).

FIGURE 2

LM137/LM337 3-Terminal Adjustable Negative Regulators

General Description

The LM137/LM337 are adjustable 3-terminal negative voltage regulators capable of supplying in excess of -1.5A over an output voltage range of -1.2V to -37V . These regulators are exceptionally easy to apply, requiring only 2 external resistors to set the output voltage and 1 output capacitor for frequency compensation. The circuit design has been optimized for excellent regulation and low thermal transients. Further, the LM137 series features internal current limiting, thermal shutdown and safe-area compensation, making them virtually blowout-proof against overloads.

The LM137/LM337 serve a wide variety of applications including local on-card regulation, programmable-output voltage regulation or precision current regulation. The LM137/LM337 are ideal complements to the LM117/LM317 adjustable positive regulators.

Features

- Output voltage adjustable from -1.2V to -37V
- 1.5A output current guaranteed, -55°C to $+150^\circ\text{C}$
- Line regulation typically $0.01\%/V$
- Load regulation typically 0.3%
- Excellent thermal regulation, $0.002\%/W$

- 77 dB ripple rejection
- Excellent rejection of thermal transients
- $50\text{ ppm}/^\circ\text{C}$ temperature coefficient
- Temperature-independent current limit
- Internal thermal overload protection
- 100% electrical burn-in
- Standard 3-lead transistor package
- Output is short circuit protected

LM137 Series Packages and Power Capability

Device	Package	Rated Power Dissipation	Design Load Current
LM137/337	TO-3 TO-39	20W 2W	1.5A 0.5A
LM337T	TO-220	15W	1.5A
LM337M	TO-202	7.5W	0.5A

Typical Applications

TL/H/9067-1

Full output current not available at high input-output voltages

$$-V_{OUT} = -1.25V \left(1 + \frac{R_2}{120\Omega} \right) + (-I_{ADJ} \times R_2)$$

†C1 = $1\text{ }\mu\text{F}$ solid tantalum or $10\text{ }\mu\text{F}$ aluminum electrolytic required for stability

*C2 = $1\text{ }\mu\text{F}$ solid tantalum is required only if regulator is more than $4''$ from power-supply filter capacitor

Output capacitors in the range of $1\text{ }\mu\text{F}$ to $1000\text{ }\mu\text{F}$ of aluminum or tantalum electrolytic are commonly used to provide improved output impedance and rejection of transients

LM137HV/LM337HV 3-Terminal Adjustable Negative Regulators (High Voltage)

General Description

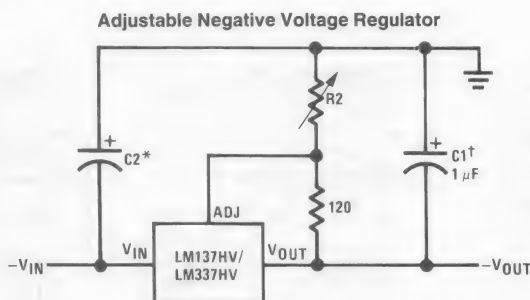

The LM137HV/LM337HV are adjustable 3-terminal negative voltage regulators capable of supplying in excess of -1.5A over an output voltage range of -1.2V to -47V . These regulators are exceptionally easy to apply, requiring only 2 external resistors to set the output voltage and 1 output capacitor for frequency compensation. The circuit design has been optimized for excellent regulation and low thermal transients. Further, the LM137HV series features internal current limiting, thermal shutdown and safe-area compensation, making them virtually blowout-proof against overloads.

The LM137HV/LM337HV serve a wide variety of applications including local on-card regulation, programmable-output voltage regulation or precision current regulation. The LM137HV/LM337HV are ideal complements to the LM117HV/LM317HV adjustable positive regulators.

Features

- Output voltage adjustable from -1.2V to -47V
- 1.5A output current guaranteed, -55°C to $+150^\circ\text{C}$
- Line regulation typically $0.01\%/V$
- Load regulation typically 0.3%
- Excellent thermal regulation, $0.002\%/W$
- 77 dB ripple rejection
- Excellent rejection of thermal transients
- $50\text{ ppm}/^\circ\text{C}$ temperature coefficient
- Temperature-independent current limit
- Internal thermal overload protection
- 100% electrical burn-in
- Standard 3-lead transistor package
- Output short circuit protected

Typical Applications

TL/H/9066-1

$$-V_{OUT} = -1.25V \left(1 + \frac{R_2}{120\Omega} \right) + \left[-I_{Adj}(R_2) \right]$$

†C1 = $1\text{ }\mu\text{F}$ solid tantalum or $10\text{ }\mu\text{F}$ aluminum electrolytic required for stability. Output capacitors in the range of $1\text{ }\mu\text{F}$ to $1000\text{ }\mu\text{F}$ of aluminum or tantalum electrolytic are commonly used to provide improved output impedance and rejection of transients.

*C2 = $1\text{ }\mu\text{F}$ solid tantalum is required only if regulator is more than $4''$ from power-supply filter capacitor.

Note 1: Unless otherwise specified, these specifications apply: $-55^\circ\text{C} \leq T_J \leq +150^\circ\text{C}$ for the LM137HV, $0^\circ\text{C} \leq T_J \leq +125^\circ\text{C}$ for the LM337HV; $V_{IN} - V_{OUT} = 5\text{V}$; and $I_{OUT} = 0.1\text{A}$ for the TO-39 package and $I_{OUT} = 0.5\text{A}$ for the TO-3 package. Although power dissipation is internally limited, these specifications are applicable for power dissipations of 2W for the TO-39 and 20W for the TO-3. I_{MAX} is 1.5A for the TO-3 package and 0.2A for the TO-39 package.

Note 2: Regulation is measured at constant junction temperature, using pulse testing with a low duty cycle. Changes in output voltage due to heating effects are covered under the specification for thermal regulations. Load regulation is measured on the output pin at a point $\frac{1}{16}$ " below the base of the TO-3 and TO-39 packages.

Note 3: Refer to RETS237HVH drawing for LM137HVH or RETS137HVK for LM137HVK military specifications.

Schematic Diagram

Thermal Regulation

When power is dissipated in an IC, a temperature gradient occurs across the IC chip affecting the individual IC circuit components. With an IC regulator, this gradient can be especially severe since power dissipation is large. Thermal regulation is the effect of these temperature gradients on output voltage (in percentage output change) per Watt of power change in a specified time. Thermal regulation error is independent of electrical regulation or temperature coefficient, and occurs within 5 ms to 50 ms after a change in power dissipation. Thermal regulation depends on IC layout as well as electrical design. The thermal regulation of a voltage regulator is defined as the percentage change of V_{OUT} , per Watt, within the first 10 ms after a step of power is applied. The LM137HV's specification is 0.02%/W, max.

In Figure 1, a typical LM137HV's output drifts only 3 mV (or 0.03% of $V_{OUT} = -10V$) when a 10W pulse is applied for 10 ms. This performance is thus well inside the specification limit of $0.02\%/W \times 10W = 0.2\%$ max. When the 10W pulse is ended, the thermal regulation again shows a 3 mV step as the LM137HV chip cools off. Note that the load regulation error of about 8 mV (0.08%) is additional to the thermal regulation error. In Figure 2, when the 10W pulse is applied for 100 ms, the output drifts only slightly beyond the drift in the first 10 ms, and the thermal error stays well within 0.1% (10 mV).

Typical Performance Characteristics (H and K-STEEL Package)

LM138/LM338 5 Amp Adjustable Power Regulators

General Description

The LM138/LM338 are adjustable 3-terminal positive voltage regulators capable of supplying in excess of 5A over a 1.2V to 32V output range. They are exceptionally easy to use and require only 2 resistors to set the output voltage. Careful circuit design has resulted in outstanding load and line regulation—comparable to many commercial power supplies. The LM138 family is supplied in a standard 3-lead transistor package.

A unique feature of the LM138 family is time-dependent current limiting. The current limit circuitry allows peak currents of up to 12A to be drawn from the regulator for short periods of time. This allows the LM138 to be used with heavy transient loads and speeds start-up under full-load conditions. Under sustained loading conditions, the current limit decreases to a safe value protecting the regulator. Also included on the chip are thermal overload protection and safe area protection for the power transistor. Overload protection remains functional even if the adjustment pin is accidentally disconnected.

Normally, no capacitors are needed unless the device is situated more than 6 inches from the input filter capacitors in which case an input bypass is needed. An optional output capacitor can be added to improve transient response. The adjustment terminal can be bypassed to achieve very high ripple rejections ratios which are difficult to achieve with standard 3-terminal regulators.

Besides replacing fixed regulators or discrete designs, the LM138 is useful in a wide variety of other applications. Since the regulator is "floating" and sees only the input-to-output differential voltage, supplies of several hundred volts can be regulated as long as the maximum input to output differential is not exceeded, i.e., do not short-circuit output to ground.

The LM138/LM338 are packaged in standard steel TO-3 transistor packages. The LM138 is rated for operation from -55°C to $+150^{\circ}\text{C}$, and the LM338 from 0°C to $+125^{\circ}\text{C}$.

Features

- Guaranteed 7A peak output current
- Guaranteed 5A output current
- Adjustable output down to 1.2V
- Line regulation typically 0.005%/V
- Load regulation typically 0.1%
- Guaranteed thermal regulation
- Current limit constant with temperature
- 100% electrical burn-in in thermal limit
- Standard 3-lead transistor package
- Output is short-circuit protected

Typical Applications

1.2V–25V Adjustable Regulator

TL/H/9060-1

Full output current not available at high input-output voltages

†Optional—improves transient response. Output capacitors in the range of $1\ \mu\text{F}$ to $1000\ \mu\text{F}$ of aluminum or tantalum electrolytic are commonly used to provide improved output impedance and rejection of transients.

*Needed if device is more than 6 inches from filter capacitors.

$$\dagger\dagger V_{\text{OUT}} = 1.25\text{V} \left(1 + \frac{R_2}{R_1} \right) + I_{\text{ADJ}} (R_2)$$

** $R_1 = 240\ \Omega$ for LM138. R_1, R_2 as an assembly can be ordered from Bourns:

Note 1: Unless otherwise specified, these specifications apply –55°C ≤ T_J ≤ +150°C for the LM138, –25°C ≤ T_J ≤ +150°C for the LM338, $V_{IN} - V_{OUT} = 5\text{V}$ and $I_{OUT} = 2.5\text{A}$. Although power dissipation is internally limited, these specifications are applicable for power dissipations up to 50W.

Note 2: Regulation is measured at constant junction temperature. Changes in output voltage due to heating effects are taken into account separately by thermal regulation.

Note 3: Selected devices with tightened tolerance reference voltage available.

Note 4: Refer to RETS138K for military specification of LM138K.

Typical Performance Characteristics

TL/H/9060-4

Typical Performance Characteristics (Continued)

Application Hints

In operation, the LM138 develops a nominal 1.25V reference voltage, V_{REF} , between the output and adjustment terminal. The reference voltage is impressed across program resistor R_1 and, since the voltage is constant, a constant current I_1 then flows through the output set resistor R_2 , giving an output voltage of

$$V_{OUT} = V_{REF} \left(1 + \frac{R_2}{R_1} \right) + I_{ADJ} R_2.$$

TL/H/9080-6

FIGURE 1

Since the 50 μ A current from the adjustment terminal represents an error term, the LM138 was designed to minimize I_{ADJ} and make it very constant with line and load changes. To do this, all quiescent operating current is returned to the output establishing a minimum load current requirement. If there is insufficient load on the output, the output will rise.

External Capacitors

An input bypass capacitor is recommended. A 0.1 μ F disc or 1 μ F solid tantalum on the input is suitable input bypassing for almost all applications. The device is more sensitive to the absence of input bypassing when adjustment or output capacitors are used but the above values will eliminate the possibility of problems.

The adjustment terminal can be bypassed to ground on the LM138 to improve ripple rejection. This bypass capacitor prevents ripple from being amplified as the output voltage is increased. With a 10 μ F bypass capacitor 75 dB ripple rejection is obtainable at any output level. Increases over 20 μ F do not appreciably improve the ripple rejection at frequencies above 120 Hz. If the bypass capacitor is used, it is sometimes necessary to include protection diodes to prevent the capacitor from discharging through internal low current paths and damaging the device.

In general, the best type of capacitors to use are solid tantalum. Solid tantalum capacitors have low impedance even at high frequencies. Depending upon capacitor construction, it takes about 25 μ F in aluminum electrolytic to equal 1 μ F solid tantalum at high frequencies. Ceramic capacitors are also good at high frequencies; but some types have a large decrease in capacitance at frequencies around 0.5 MHz. For this reason, 0.01 μ F disc may seem to work better than a 0.1 μ F disc as a bypass.

Although the LM138 is stable with no output capacitors, like any feedback circuit, certain values of external capacitance can cause excessive ringing. This occurs with values between 500 pF and 5000 pF. A 1 μ F solid tantalum (or 25 μ F aluminum electrolytic) on the output swamps this effect and insures stability.

Load Regulation

The LM138 is capable of providing extremely good load regulation but a few precautions are needed to obtain maximum performance. The current set resistor connected between the adjustment terminal and the output terminal (usually 240 Ω) should be tied directly to the output of the regulator (case) rather than near the load. This eliminates line drops from appearing effectively in series with the reference and degrading regulation. For example, a 15V regulator with 0.05 Ω resistance between the regulator and load will have a load regulation due to line resistance of $0.05\Omega \times I_L$. If the set resistor is connected near the load the effective line resistance will be $0.05\Omega (1 + R_2/R_1)$ or in this case, 11.5 times worse.

Figure 2 shows the effect of resistance between the regulator and 240 Ω set resistor.

TL/H/9080-7

FIGURE 2. Regulator with Line Resistance in Output Lead

With the TO-3 package, it is easy to minimize the resistance from the case to the set resistor, by using 2 separate leads to the case. The ground of R_2 can be returned near the ground of the load to provide remote ground sensing and improve load regulation.

Protection Diodes

When external capacitors are used with any IC regulator it is sometimes necessary to add protection diodes to prevent the capacitors from discharging through low current points into the regulator. Most 20 μ F capacitors have low enough internal series resistance to deliver 20A spikes when shorted. Although the surge is short, there is enough energy to damage parts of the IC.

When an output capacitor is connected to a regulator and the input is shorted, the output capacitor will discharge into the output of the regulator. The discharge current depends on the value of the capacitor, the output voltage of the regulator, and the rate of decrease of V_{IN} . In the LM138 this discharge path is through a large junction that is able to sustain 25A surge with no problem. This is not true of other types of positive regulators. For output capacitors of 100 μ F or less at output of 15V or less, there is no need to use diodes.

The bypass capacitor on the adjustment terminal can discharge through a low current junction. Discharge occurs when either the input or output is shorted. Internal to the LM138 is a 50 Ω resistor which limits the peak discharge current. No protection is needed for output voltages of 25V or less and 10 μ F capacitance. Figure 3 shows an LM138 with protection diodes included for use with outputs greater than 25V and high values of output capacitance.

LM140A/LM140/LM340A/LM340 Series 3-Terminal Positive Regulators

General Description

The LM140A/LM140/LM340A/LM340 series of positive 3-terminal voltage regulators are designed to provide superior performance as compared to the previously available 78XX series regulator. Computer programs were used to optimize the electrical and thermal performance of the packaged IC which results in outstanding ripple rejection, superior line and load regulation in high power applications (over 15W).

With these advances in design, the LM340 is now guaranteed to have line and load regulation that is a factor of 2 better than previously available devices. Also, all parameters are guaranteed at 1A vs 0.5A output current. The LM140A/LM340A provide tighter output voltage tolerance, $\pm 2\%$ along with 0.01%/V line regulation and 0.3%/A load regulation.

Current limiting is included to limit peak output current to a safe value. Safe area protection for the output transistor is provided to limit internal power dissipation. If internal power dissipation becomes too high for the heat sinking provided, the thermal shutdown circuit takes over limiting die temperature.

Considerable effort was expended to make the LM140-XX series of regulators easy to use and minimize the number of external components. It is not necessary to bypass the output, although this does improve transient response. Input bypassing is needed only if the regulator is located far from the filter capacitor of the power supply.

Although designed primarily as fixed voltage regulators, these devices can be used with external components to obtain adjustable voltages and currents.

The entire LM140A/LM140/LM340A/LM340 series of regulators is available in the metal TO-3 power package and the

LM340A/LM340 series is also available in the TO-220 plastic power package.

For output voltages other than 5V, 12V, and 15V, the LM117 series provides an output voltage range from +1.2V to +57V.

Features

- Complete specifications at 1A load
- Output voltage tolerances of $\pm 2\%$ at $T_j = 25^\circ\text{C}$ and $\pm 4\%$ over the temperature range (LM140A/LM340A)
- Fixed output voltages available 5, 12, and 15V
- Line regulation of 0.01% of $V_{OUT}/V \Delta V_{IN}$ at 1A load (LM140A/LM340A)
- Load regulation of 0.3% of $V_{OUT}/A \Delta I_{LOAD}$ (LM140A/LM340A)
- Internal thermal overload protection
- Internal short-circuit current limit
- Output transistor safe area protection
- 100% thermal limit burn-in
- Special circuitry allows start-up even if output is pulled to negative voltage (\pm supplies)

LM140 Series Package and Power Capability

Application Hints

The LM340 is designed with thermal protection, output short-circuit protection and output transistor safe area protection. However, as with *any* IC regulator, it becomes necessary to take precautions to assure that the regulator is not inadvertently damaged. The following describes possible misapplications and methods to prevent damage to the regulator.

Shorting the Regulator Input: When using large capacitors at the output of these regulators, a protection diode connected input to output (Figure 1) may be required if the input is shorted to ground. Without the protection diode, an input short will cause the input to rapidly approach ground potential, while the output remains near the initial V_{OUT} because of the stored charge in the large output capacitor. The capacitor will then discharge through a large internal input to output diode and parasitic transistors. If the energy released by the capacitor is large enough, this diode, low current metal and the regulator will be destroyed. The fast diode in Figure 1 will shunt most of the capacitors discharge current around the regulator. Generally no protection diode is required for values of output capacitance $\leq 10 \mu\text{F}$.

FIGURE 1. Input Short

TL/H/7781-8

Raising the Output Voltage above the Input Voltage: Since the output of the LM340 does not sink current, forcing the output high can cause damage to internal low current paths in a manner similar to that just described in the "Shorting the Regulator Input" section.

Regulator Floating Ground (Figure 2): When the ground pin alone becomes disconnected, the output approaches the unregulated input, causing possible damage to other circuits connected to V_{OUT} . If ground is reconnected with power "ON", damage may also occur to the regulator. This fault is most likely to occur when plugging in regulators or modules with on card regulators into powered up sockets. Power should be turned off first, thermal limit ceases operating, or ground should be connected first if power must be left on.

Transient Voltages: If transients exceed the maximum rated input voltage of the 340, or reach more than 0.8V below ground and have sufficient energy, they will damage the regulator. The solution is to use a large input capacitor, a series input breakdown diode, a choke, a transient suppressor or a combination of these.

LM140L/LM340L Series 3-Terminal Positive Regulators

General Description

The LM140L series of three terminal positive regulators is available with several fixed output voltages making them useful in a wide range of applications. The LM140LA is an improved version of the LM78LXX series with a tighter output voltage tolerance (specified over the full military temperature range), higher ripple rejection, better regulation and lower quiescent current. The LM140LA regulators have $\pm 2\%$ V_{OUT} specification, $0.04\%/V$ line regulation, and $0.01\%/mA$ load regulation. When used as a zener diode/resistor combination replacement, the LM140LA usually results in an effective output impedance improvement of two orders of magnitude, and lower quiescent current. These regulators can provide local on card regulation, eliminating the distribution problems associated with single point regulation. The voltages available allow the LM140LA to be used in logic systems, instrumentation, Hi-Fi, and other solid state electronic equipment. Although designed primarily as fixed voltage regulators, these devices can be used with external components to obtain adjustable voltages and currents.

The LM140LA/LM340LA are available in the low profile metal three lead TO-39 (H) and the LM340LA are also available in the plastic TO-92 (Z). With adequate heat sinking the regulator can deliver 100 mA output current. Current limiting is included to limit the peak output current to a safe value. Safe area protection for the output transistor is provided to limit internal power dissipation. If internal power dissipation

becomes too high for the heat sinking provided, the thermal shut-down circuit takes over, preventing the IC from overheating.

For applications requiring other voltages, see LM117L Data Sheet.

Features

- Line regulation of $0.04\%/V$
- Load regulation of $0.01\%/mA$
- Output voltage tolerances of $\pm 2\%$ at $T_j = 25^\circ C$ and $\pm 4\%$ over the temperature range (LM140LA)
 $\pm 3\%$ over the temperature range (LM340LA)
- Output current of 100 mA
- Internal thermal overload protection
- Output transistor safe area protection
- Internal short circuit current limit
- Available in metal TO-39 low profile package (LM140LA/LM340LA) and plastic TO-92 (LM340LA)

Note 1: Thermal resistance of H-package is typically $26^\circ\text{C}/\text{W}$ θ_{JC} , $250^\circ\text{C}/\text{W}$ θ_{JA} still air, and $94^\circ\text{C}/\text{W}$ θ_{JA} 400 lf/min of air. For the Z-package is $60^\circ\text{C}/\text{W}$ θ_{JC} , $232^\circ\text{C}/\text{W}$ θ_{JA} still air, and $88^\circ\text{C}/\text{W}$ θ_{JA} at 400 lf/min of air. The maximum junction temperature shall not exceed 125°C on electrical parameters.

Note 2: The maximum steady state usable output current and input voltage are very dependent on the heat sinking and/or lead length of the package. The data above represent pulse test conditions with junction temperatures as indicated at the initiation of tests.

Note 3: It is recommended that a minimum load capacitor of $0.01\text{ }\mu\text{F}$ be used to limit the high frequency noise bandwidth.

Note 4: The temperature coefficient of V_{OUT} is typically within 0.01% $V_O/^\circ\text{C}$.

Note 5: Refer to RETS140-12H for LM140LAH-12, RETS140-15H for LM140LAH-15 or RETS140-15H for LM140LAH-5.0 military specification.

LM145/LM345 Negative Three Amp Regulator

General Description

The LM145 is a three-terminal negative regulator with a fixed output voltage of $-5V$ or $-5.2V$, and up to 3A load current capability. This device needs only one external component—a compensation capacitor at the output, making it easy to apply. Worst case guarantees on output voltage deviation due to any combination of line, load or temperature variation assure satisfactory system operation.

Exceptional effort has been made to make the LM145 immune to overload conditions. The regulator has current limiting which is independent of temperature, combined with thermal overload protection. Internal current limiting protects against momentary faults while thermal shutdown prevents junction temperatures from exceeding safe limits during prolonged overloads.

Although primarily intended for fixed output voltage applications, the LM145 may be programmed for higher output voltages with a simple resistive divider. The low quiescent drain

current of the device allows this technique to be used with good regulation.

The LM145 comes in a hermetic TO-3 package rated at 25W. A reduced temperature range part LM345 is also available.

Features

- Output voltage accurate to better than $\pm 2\%$
- Current limit constant with temperature
- Internal thermal shutdown protection
- Operates with input-output voltage differential of 2.8V at full rated load over full temperature range
- Regulation guaranteed with 25W power dissipation
- 3A output current guaranteed
- Only one external component needed
- 100% electrical burn-in

Long Term Stability			5	50		5	50	mV
Thermal Resistance Junction to Case			2			2		°C/W

Note 1: Unless otherwise specified, these specifications apply: $-55^\circ\text{C} \leq T_j \leq +150^\circ\text{C}$ for the LM145 and $0^\circ\text{C} \leq T_j \leq +125^\circ\text{C}$ for the LM345. $V_{IN} = 7.5\text{V}$ and $I_{OUT} = 5\text{ mA}$. Although power dissipation is internally limited, electrical specifications apply only for power levels up to 25W. For calculations of junction temperature rise due to power dissipation, use a thermal resistance of 35°C/W for the TO-3 with no heat sink. With a heat sink, use 2°C/W for junction to case thermal resistance.

Note 2: Regulation is measured at constant junction temperature. Changes in output voltage due to heating effects must be taken into account separately. To ensure constant junction temperature, pulse testing with a low duty cycle is used.

Note 3: Refer to RETS145K-5.2V for LM145K-5.2V or RETS145K-5V for LM145K-5.0 military specifications.

LM150/LM350 3 Amp Adjustable Power Regulators

General Description

The LM150/LM350 are adjustable 3-terminal positive voltage regulators capable of supplying in excess of 3A over a 1.2V to 33V output range. They are exceptionally easy to use and require only 2 external resistors to set the output voltage. Further, both line and load regulation are comparable to discrete designs. Also, the LM150 is packaged in standard transistor packages which are easily mounted and handled.

In addition to higher performance than fixed regulators, the LM150 series offers full overload protection available only in IC's. Included on the chip are current limit, thermal overload protection and safe area protection. All overload protection circuitry remains fully functional even if the adjustment terminal is accidentally disconnected.

Normally, no capacitors are needed unless the device is situated more than 6 inches from the input filter capacitors in which case an input bypass is needed. An optional output capacitor can be added to improve transient response. The adjustment terminal can be bypassed to achieve very high ripple rejection ratios which are difficult to achieve with standard 3-terminal regulators.

Besides replacing fixed regulators or discrete designs, the LM150 is useful in a wide variety of other applications. Since the regulator is "floating" and sees only the input-to-output differential voltage, supplies of several hundred volts can be regulated as long as the maximum input to output differential is not exceeded, i.e., avoid short-circuiting the output.

Also, it makes an especially simple adjustable switching regulator, a programmable output regulator, or by connecting a fixed resistor between the adjustment pin and output, the LM150 can be used as a precision current regulator. Supplies with electronic shutdown can be achieved by clamping the adjustment terminal to ground which programs the output to 1.2V where most loads draw little current.

The LM150K/LM350K are packaged in standard steel TO-3 transistor packages. The LM350T is packaged in a TO-220 plastic package. The LM150 is rated for operation from -55°C to +150°C, and the LM350 from 0°C to +125°C.

Features

- Adjustable output down to 1.2V
- Guaranteed 3A output current
- Line regulation typically 0.005%/V
- Load regulation typically 0.1%
- Guaranteed thermal regulation
- Output is short circuit protected
- Current limit constant with temperature
- 100% electrical burn-in in thermal limit
- Eliminates the need to stock many voltages
- Standard 3-lead transistor package
- 86 dB ripple rejection

Typical Applications

1.2V—25V Adjustable Regulator

TL/H/9061-1

Full output current not available at high input-output voltages.

†Optional—improves transient response. Output capacitors in the range of 1 μF to 1000 μF of aluminum or tantalum electrolytic are commonly used to provide improved output impedance and rejection of transients.

*Needed if device is more than 6 inches from filter capacitors.

$$\dagger\dagger V_{OUT} = 1.25V \left(1 + \frac{R2}{R1} \right) + I_{ADJ}(R2)$$

Note: Usually R1 = 240Ω for LM150 and R1 = 120Ω for LM350.

	T Package		50			50		$^\circ\text{C}/\text{W}$

Note 1: Unless otherwise specified, these specifications apply $-55^\circ\text{C} \leq T_j \leq +150^\circ\text{C}$ for the LM150, $0^\circ\text{C} \leq T_j \leq 125^\circ\text{C}$ for the LM350. $V_{\text{IN}} - V_{\text{OUT}} = 5\text{V}$, and $I_{\text{OUT}} = 10\text{mA}$. These specifications are applicable for power dissipations up to 30W for the K package and 25W for the T package. Power dissipation is guaranteed at these values up to 15 volts input-output differential. Above 15 volts differential, power dissipation will be limited by internal protection circuitry.

Note 2: Regulation is measured at constant junction temperature. Changes in output voltage due to heating effects must be taken into account separately. Pulse testing with low duty cycle is used.

Note 3: Refer to RETS150K drawing for military specifications of the LM150K.

Typical Performance Characteristics

Application Hints

In operation, the LM150 develops a nominal 1.25V reference voltage, V_{REF} , between the output and adjustment terminal. The reference voltage is impressed across program resistor R1 and, since the voltage is constant, a constant current I_1 then flows through the output set resistor R2, giving an output voltage of

$$V_{OUT} = V_{REF} \left(1 + \frac{R_2}{R_1} \right) + I_{ADJ} R_2$$

TL/H/9061-7

FIGURE 1

Since the 50 μ A current from the adjustment terminal represents an error term, the LM150 was designed to minimize I_{ADJ} and make it very constant with line and load changes. To do this, all quiescent operating current is returned to the output establishing a minimum load current requirement. If there is insufficient load on the output, the output will rise.

EXTERNAL CAPACITORS

An input bypass capacitor is recommended. A 0.1 μ F disc or 1 μ F solid tantalum on the input is suitable input bypassing for almost all applications. The device is more sensitive to the absence of input bypassing when adjustment or output capacitors are used but the above values will eliminate the possibility of problems.

The adjustment terminal can be bypassed to ground on the LM150 to improve ripple rejection. This bypass capacitor prevents ripple from being amplified as the output voltage is increased. With a 10 μ F bypass capacitor 86 dB ripple rejection is obtainable at any output level. Increases over 10 μ F do not appreciably improve the ripple rejection at frequencies above 120 Hz. If the bypass capacitor is used, it is sometimes necessary to include protection diodes to prevent the capacitor from discharging through internal low current paths and damaging the device.

In general, the best type of capacitors to use is solid tantalum. Solid tantalum capacitors have low impedance even at high frequencies. Depending upon capacitor construction, it takes about 25 μ F in aluminum electrolytic to equal 1 μ F solid tantalum at high frequencies. Ceramic capacitors are also good at high frequencies, but some types have a large decrease in capacitance at frequencies around 0.5 MHz. For this reason, 0.01 μ F disc may seem to work better than a 0.1 μ F disc as a bypass.

Although the LM150 is stable with no output capacitors, like any feedback circuit, certain values of external capacitance can cause excessive ringing. This occurs with values between 500 pF and 5000 pF. A 1 μ F solid tantalum (or 25 μ F aluminum electrolytic) on the output swamps this effect and insures stability.

LOAD REGULATION

The LM150 is capable of providing extremely good load regulation but a few precautions are needed to obtain maximum performance. The current set resistor connected between the adjustment terminal and the output terminal (usually 240 Ω) should be tied directly to the output (case) of the regulator rather than near the load. This eliminates line drops from appearing effectively in series with the reference and degrading regulation. For example, a 15V regulator with 0.05 Ω resistance between the regulator and load will have a load regulation due to line resistance of $0.05 \Omega \times I_L$. If the set resistor is connected near the load the effective line resistance will be $0.05 \Omega (1 + R_2/R_1)$ or in this case, 11.5 times worse.

Figure 2 shows the effect of resistance between the regulator and 240 Ω set resistor.

TL/H/9061-8

FIGURE 2. Regulator with Line Resistance in Output Lead

With the TO-3 package, it is easy to minimize the resistance from the case to the set resistor, by using two separate leads to the case. The ground of R2 can be returned near the ground of the load to provide remote ground sensing and improve load regulation.

PROTECTION DIODES

When external capacitors are used with any IC regulator it is sometimes necessary to add protection diodes to prevent the capacitors from discharging through low current points into the regulator. Most 10 μ F capacitors have low enough internal series resistance to deliver 20A spikes when shorted. Although the surge is short, there is enough energy to damage parts of the IC.

When an output capacitor is connected to a regulator and the input is shorted, the output capacitor will discharge into the output of the regulator. The discharge current depends on the value of the capacitor, the output voltage of the regulator, and the rate of decrease of V_{IN} . In the LM150, this discharge path is through a large junction that is able to sustain 25A surge with no problem. This is not true of other types of positive regulators. For output capacitors of 25 μ F or less, there is no need to use diodes.

The bypass capacitor on the adjustment terminal can discharge through a low current junction. Discharge occurs when either the input or output is shorted. Internal to the LM150 is a 50 Ω resistor which limits the peak discharge current. No protection is needed for output voltages of 25V or less and 10 μ F capacitance. Figure 3 shows an LM150 with protection diodes included for use with outputs greater than 25V and high values of output capacitance.

LM196/LM396 10 Amp Adjustable Voltage Regulator

General Description

The LM196 is a 10 amp regulator, adjustable from 1.25V to 15V, which uses a revolutionary new IC fabrication structure to combine high power discrete transistor technology with modern monolithic linear IC processing. This combination yields a high-performance single-chip regulator capable of supplying in excess of 10 amps and operating at power levels up to 70 watts. The regulators feature on-chip trimming of reference voltage to $\pm 0.8\%$ and simultaneous trimming of reference temperature drift to 30 ppm/ $^{\circ}\text{C}$ typical. Thermal interaction between control circuitry and the pass transistor which affects the output voltage has been reduced to extremely low levels by strict attention to isothermal layout. This interaction, called thermal regulation, is 100% tested.

These new regulators have all the protection features of popular lower power adjustable regulators such as LM117 and LM138, including current limiting and thermal limiting. The combination of these features makes the LM196 immune to blowout from output overloads or shorts, even if the adjustment pin is accidentally disconnected. All devices are "burned-in" in thermal shutdown to guarantee proper operation of these protective features under actual overload conditions.

Output voltage is continuously adjustable from 1.25V to 15V. Higher output voltages are possible if the maximum input-output voltage differential specification is not exceeded. Full load current of 10A is available at all output voltages, subject only to the maximum power limit of 70W and of course, maximum junction temperature.

The LM196 is exceptionally easy to use. Only two external resistors are used to set output voltage. On-chip adjustment of the reference voltage allows a much tighter specification of output voltage, eliminating any need for trimming in most cases. The regulator will tolerate an extremely wide range of reactive loads, and does not depend on external capacitors for frequency stabilization. Heat sink requirements are much less stringent, because overload situations do not have to be accounted for—only worst-case full load conditions.

The LM196 is in a TO-3 package with oversized (0.060") leads to provide best possible load regulation. Operating junction temperature range is -55°C to $+150^{\circ}\text{C}$. The LM396 is specified for a 0°C to $+125^{\circ}\text{C}$ junction temperature range.

Features

Common

- Output pre-trimmed to $\pm 0.8\%$
- 10A guaranteed output current
- 100% burn-in in thermal limit
- 70W maximum power dissipation
- Adjustable output—1.25V to 15V
- Internal current and power limiting
- Guaranteed thermal resistance
- Output voltage guaranteed under worst-case conditions
- Output is short circuit protected

Typical Applications

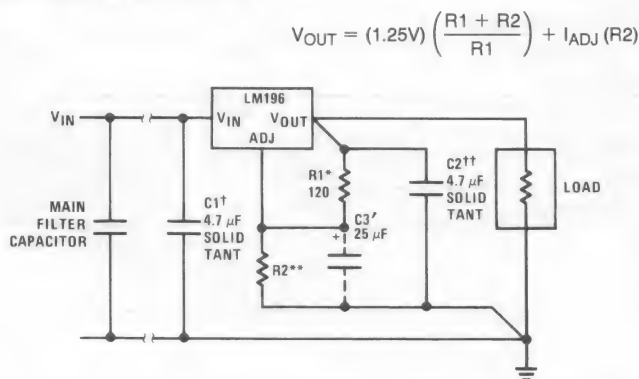

FIGURE 1. Basic 1.25V to 15V Regulator

*For best TC of V_{OUT} , R_1 should be wirewound or metal film, 1% or better.

** R_2 should be same type as R_1 , with TC tracking of 30 ppm/ $^{\circ}\text{C}$ or better.

† C_1 is necessary only if main filter capacitor is more than 6" away, assuming #18 or larger leads.

†† C_2 is not absolutely necessary, but is suggested to lower high frequency output impedance. Output capacitors in the range of 1 μF to 1000 μF of aluminum or tantalum electrolytic are commonly used to provide improved output impedance and rejection of transients.

‡ C_3 improves ripple rejection, output impedance, and noise. C_2 should be 1 μF or larger close to the regulator if C_3 is used.

Drop-Out Voltage LM196/LM396	$I_{OUT} = 10A$, Full Temperature Range		2.1	2.5 2.75		2.1	2.5 2.75	V

Note 1: Unless otherwise stated, these specifications apply for $T_J = 25^\circ C$, $V_{IN} - V_{OUT} = 5V$, $I_{OUT} = 10mA$ to $10A$.

Note 2: This is a worst-case specification which includes all effects due to input voltage, output current, temperature, and power dissipation. Maximum power (P_{MAX}) is specified under Electrical Characteristics.

Note 3: Line regulation is measured on a short-pulse, low-duty-cycle basis to maintain constant junction temperature. Changes in output voltage due to thermal gradients or temperature changes must be taken into account separately. See discussion of Line Regulation under Application Hints.

Note 4: Load regulation on the 2-pin package is determined primarily by the voltage drop along the output pin. Specifications apply for an external Kelvin sense connection at a point on the output pin $\frac{1}{4}$ " from the bottom of the package. Testing is done on a short-pulse-width, low-duty-cycle basis to maintain constant junction temperature. Changes in output voltage due to thermal gradients or temperature changes must be taken into account separately. See discussion of Load Regulation under Application Hints.

Note 5: Ripple rejection is measured with the adjustment pin bypassed with $25 \mu F$ capacitor, and is therefore independent of output voltage. With no load or bypass capacitor, ripple rejection is determined by line regulation and may be calculated from: $RR = 20 \log_{10} [100/(K \times V_{OUT})]$ where K is line regulation expressed in %/V. At frequencies below 100 Hz, ripple rejection may be limited by thermal effects, if load current is above 1A.

Note 6: Thermal regulation is defined as the change in output voltage during the time period of 0.2 ms to 20 ms after a change in power dissipation in the regulator, due to either a change in input voltage or output current. See graphs and discussion of thermal effects under Application Hints.

Note 7: Adjustment pin current change is specified for the worst-case combination of input voltage, output current, and power dissipation. Changes due to temperature must be taken into account separately. See graph of adjustment pin current vs temperature.

Note 8: Current limit is measured 10 ms after a short is applied to the output. DC measurements may differ slightly due to the rapidly changing junction temperature, tending to drop slightly as temperature increases. A minimum available load current of 10A is guaranteed over the full temperature range as long as power dissipation does not exceed 70W, and $V_{IN} - V_{OUT}$ is less than 7.0V.

Note 9: Minimum load current of 10 mA is normally satisfied by the resistor divider which sets up output voltage.

Note 10: Total thermal resistance, junction-to-ambient, will include junction-to-case thermal resistance plus interface resistance and heat sink resistance. See discussion of Heat Sinking under Application Hints.

Note 11: Although power dissipation is internally limited, electrical specifications apply only for power dissipation up to the limits shown. Derating with temperature is a function of both power transistor temperature and control area temperature, which are specified differently. See discussion of Heat Sinking under Application Hints. For $V_{IN} - V_{OUT}$ less than 7V, power dissipation is limited by current limit of 10A.

Note 12: Dropout voltage is input-output voltage differential measured at a forced reference voltage of 1.15V, with a 10A load, and is a measurement of the minimum input/output differential at full load.

Application Hints

Further improvements in efficiency can be obtained by using Schottky diodes or high efficiency diodes with lower forward voltage, combined with larger filter capacitors to reduce ripple. However, this reduces the voltage difference between input and drive pins and may not allow sufficient voltage to fully saturate the pass transistor. Special transformers are available from Signal Transformer that have a 1V tap on the output winding to provide the extra voltage for the drive pin. The transformers are available as standard items for 5V applications at 5A, 10A and 20A. Other voltages are available on special request.

Heat Sinking

Because of its extremely high power dissipation capability, the *major limitation* in the load driving capability of the LM196 is *heat sinking*. Previous regulators such as LM109, LM340, LM117, etc., had internal power limiting circuitry which limited power dissipation to about 30W. The LM196

is guaranteed to dissipate up to 70W continuously, as long as the maximum junction temperature limit is not exceeded. This requires careful attention to all sources of thermal resistance from junction-to-ambient, including junction-to-case resistance, case-to-heat sink interface resistance (0.1–1.0°C/W), and heat sink resistance itself. A good thermal joint compound such as Wakefield type 120 or Thermalloy Thermocote must be used when mounting the LM196, especially if an electrical insulator is used to isolate the regulator from the heat sink. Interface resistance without this compound will be no better than 0.5°C/W, and probably much worse. With the compound, and no insulator, interface resistance will be 0.2°C/W or less, assuming 0.005" or less combined flatness run-out of TO-3 and heat sink. Proper torquing of the mounting bolts is important to achieve minimum thermal resistance. Four to six inch pounds is recommended. Keep in mind that good electrical, as well as thermal, contact must be made to the case.

Application Hints (Continued)

The actual heat sink chosen for the LM196 will be determined by the worst-case continuous full load current, input voltage and maximum ambient temperature. Overload or short circuit output conditions do not normally have to be considered when selecting a heat sink because the thermal shutdown built into the LM196 will protect it under these conditions. An exception to this is in situations where the regulator must recover very quickly from overload. The LM196 may take some time to recover to within specified output tolerance following an extended overload, if the regulator is cooling from thermal shutdown temperature (approximately 175°C) to specified operating temperature (125°C or 150°C). The procedure for heat sink selection is as follows:

Calculate worst-case *continuous* average power dissipation in the regulator from $P = (V_{IN} - V_{OUT}) \times (I_{OUT})$. To do this, you must know the raw power supply voltage/current characteristics fairly accurately. For example, consider a 10V output with 15V nominal input voltage. At full load of 10A, the regulator will dissipate $P = (15 - 10) \times (10) = 50W$. If input voltage rises by 10%, power dissipation will increase to $(16.5 - 10) \times (10) = 65W$, a 30% increase. It is strongly suggested that a raw supply be assembled and tested to determine its average DC output voltage *under full load with maximum line voltage*. Do not over-design by using unloaded voltage as a worst-case, since the regulator will not be dissipating any power under no load conditions. Worst-case regulator dissipation normally occurs under full load conditions except when the effective DC resistance of the raw supply ($\Delta V/\Delta I$) is larger than $(V_{IN}^* - V_{OUT})/2I_{IL}$, where V_{IN}^* is the lightly-loaded raw supply voltage and I_{IL} is full load current. For $(V_{IN}^* - V_{OUT}) = 5V - 8V$, and $I_{IL} = 5A-10A$, this gives a resistance of 0.25Ω to 0.8Ω. If raw supply resistance is higher than this, the regulator power dissipation may be less at full load current, then at some intermediate current, due to the large drop in input voltage. Fortunately, most well designed raw supplies have low enough output resistance that regulator dissipation does maximize at full load current, or very close to it, so tedious testing is not usually required to find worst-case power dissipation.

A very important consideration is the size of the filter capacitor in the raw supply. At these high current levels, capacitor size is usually dictated by ripple current ratings rather than just obtaining a certain ripple voltage. Capacitor ripple current (rms) is 2-3 times the DC output current of the filter. If the capacitor has just 0.05Ω DC resistance, this can cause 30W internal power dissipation at 10A output current. Capacitor life is very sensitive to operating temperature, decreasing by a factor of two for each 15°C rise in internal temperature. Since capacitor life is not all that great to start with, it is obvious that a small capacitor with a large internal temperature rise is inviting very short mean-time-to-failure. A second consideration is the loss of usable input voltage to the regulator. If the capacitor is small, the large dips in the input voltage may cause the LM196 to drop out of regulation. 2000 μF per ampere of load current is the *minimum* recommended value, yielding about 2 Vp-p ripple of 120 Hz. Larger values will have longer life and the reduced ripple will allow lower DC input voltage to the regulator, with subse-

quent cost savings in the transformer and heat sink. Sometimes several capacitors in parallel are better to decrease series resistance and increase heat dissipating area.

After the raw supply characteristics have been determined, and worst-case power dissipation in the LM196 is known, the heat sink thermal resistance can be found from the graphs titled Maximum Heat Sink Thermal Resistance. These curves indicate the minimum size heat sink required as a function of ambient temperature. They are derived from a case-to-control area thermal resistance of 0.5°C/W and a case-to-power transistor thermal resistance of 1.2°C/W. 0.2°C/W is assumed for interface resistance. A maximum control area temperature of 150°C is used for the LM196 and 125°C for the LM396. Maximum power transistor temperature is 200°C for the LM196 and 175°C for the LM396. For conservative designs, it is suggested that when using these curves, you assume an ambient temperature 25°C-50°C higher than is actually anticipated, to avoid running the regulator right at its design limits of operating temperature.

A quick look at the curves show that heat sink resistance (θ_{SA}) will normally fall into the range of 0.2°C/W-1.5°C/W. These are *not* small heat sinks. A model 441, for instance, which is sold by several manufacturers, has a θ_{SA} of 0.6°C/W with natural convection and is about five inches on a side. Smaller sinks are more volumetrically efficient, and larger sinks, less so. A rough formula for estimating the volume of heat sink required is: $V = 50/\theta_{SA}^{1.5}$ CU. IN. This holds for natural convection only. If the heat sink is inside a small sealed enclosure, θ_{SA} will increase substantially because the air is not free to form natural convection currents. Fan-forced convection can reduce θ_{SA} by a factor of two at 200 FPM air velocity, and by four at 1000 FPM.

Ripple Rejection

Ripple rejection at the normal ripple frequency of 120 Hz is a function of both electrical and thermal effects in the LM196. If the adjustment pin is not bypassed with a capacitor, it is also dependent on output voltage. A 25 μF capacitor from the adjustment pin to ground will make ripple rejection independent of output voltage for frequencies above 100 Hz. If lower ripple frequencies are encountered, the capacitor should be increased proportionally.

To keep in mind that the bypass capacitor on the adjustment pin will limit the turn-on time of the regulator. A 25 μF capacitor, combined with the output divider resistance, will give an extended output voltage settling time following the application of input power.

Load Regulation (LM196/LM396)

Because the LM196 is a three-terminal device, it is not possible to provide true remote load sensing. Load regulation will be limited by the resistance of the output pin and the wire connecting the regulator to the load. For the data sheet specification, regulation is measured 1/4" from the bottom of the package on the output pin. Negative side sensing is a true Kelvin connection, with the bottom of the output divider returned to the negative side of the load.

Application Hints (Continued)

Although it may not be immediately obvious, best load regulation is obtained when the top of the divider is connected *directly* to the output pin, *not to the load*. This is illustrated in Figure 2. If R1 were connected to the load, the effective resistance between the regulator and the load would be

$$(Rw) \times \left(\frac{R2 + R1}{R1} \right)$$

Rw = Line Resistance

Connected as shown, Rw is not multiplied by the divider ratio. Rw is about 0.004Ω per foot using 16 gauge wire. This translates to 40 mV/ft at 10A load current, so it is important to keep the positive lead between regulator and load as short as possible.

FIGURE 2. Proper Divider Connection

The input resistance of the sense pin is typically $6\text{ k}\Omega$, modeled as a resistor between the sense pin and the output pin. Load regulation will start to degrade if a resistance higher than 10Ω is inserted in series with the sense. This assumes a worst-case condition of 0.5V between output and sense pins. Lower differential voltage will allow higher sense series resistance.

Thermal Load Regulation

Thermal, as well as electrical, load regulation must be considered with IC regulators. Electrical load regulation occurs in microseconds, thermal regulation due to die thermal gradients occurs in the 0.2 ms-20 ms time frame, and regulation due to overall temperature changes in the die occurs over a 20 ms to 20 minute period, depending on the time constant of the heat sink used. Gradient induced load regulation is calculated from

$$\Delta V_{OUT} = (V_{IN} - V_{OUT}) \times (\Delta I_{OUT}) \times (\beta)$$

β = Thermal regulation specified on data sheet.

For $V_{IN} = 9\text{V}$, $V_{OUT} = 5\text{V}$, $\Delta I_{OUT} = 10\text{A}$, and $\beta = 0.005\%/W$, this yields a 0.2% change in output voltage. Changes in output voltage due to overall temperature rise are calculated from

$$V_{OUT} = (V_{IN} - V_{OUT}) \times (\Delta I_{OUT}) \times (TC) \times (\theta_{JA})$$

TC = Temperature coefficient of output voltage.

θ_{JA} = Thermal resistance from junction to ambient. θ_{JA} is approximately $0.5^\circ\text{C}/W + \theta$ of heat sink.

For the same conditions as before, with $TC = 0.003\%/^\circ\text{C}$, and $\theta_{JA} = 1.5^\circ\text{C}/W$, the change in output voltage will be 0.18%. Because these two thermal terms can have either polarity, they may subtract from, or add to, electrical load regulation. For worst-case analysis, they must be assumed to add. If the output of the regulator is trimmed under load, only that portion of the load that changes need be used in the previous calculations, significantly improving output accuracy.

Line Regulation

Electrical line regulation is very good on the LM196—typically less than 0.005% change in output voltage for a 1V change in input. This level of regulation is achieved only for very low load currents, however, because of thermal effects. Even with a thermal regulation of $0.002\%/W$, and a temperature coefficient of $0.003\%/^\circ\text{C}$, DC line regulation will be dominated by thermal effects as shown by the following example:

Assume $V_{OUT} = 5\text{V}$, $V_{IN} = 9\text{V}$, $I_{OUT} = 8\text{A}$

Following a 10% change in input voltage (0.9), the output will change quickly ($\leq 100\mu\text{s}$), due to electrical effects, by $(0.005\%V) \times (0.9V) = 0.0045\%$. In the next 20 ms, the output will change an additional $(0.002\%/W) \times (8A) \times (0.9V) = 0.0144\%$ due to thermal gradients across the die. After a much longer time, determined by the time constant of the heat sink, the output will change an additional $(0.003\%/^\circ\text{C}) \times (8A) \times (0.9V) \times (2^\circ\text{C}/W) = 0.043\%$ due to the temperature coefficient of output voltage and the thermal resistance from die to ambient. ($2^\circ\text{C}/W$ was chosen for this calculation). The sign of these last two terms varies from part to part, so no assumptions can be made about any cancelling effects. All three terms must be added for a proper analysis. This yields $0.0045 + 0.0144 + 0.043 = 0.062\%$ using *typical* values for thermal regulation and temperature coefficient. For worst-case analysis, the maximum data sheet specifications for thermal regulation and temperature coefficient should be used, along with the *actual* thermal resistance of the heat sink being used.

Paralleling Regulators

Direct paralleling of regulators is not normally recommended because they do not share currents equally. The regulator with the highest reference voltage will supply all the current to the load until it current limits. With an 18A load, for instance, one regulator might be operating in current limit at 16A while the second device is only carrying 2A. Power dissipation in the high current regulator is extremely high with attendant high junction temperatures. Long term reliability cannot be guaranteed under these conditions.

Quasi-paralleling may be accomplished if load regulation is not critical. The connection shown in Figure 5a will typically share to within 1A, with a worst-case of about 3A. Load regulation is degraded by 150 mV at 20A loads. An external op amp may be used as in Figure 5b to improve load regulation and provide remote sensing.

Application Hints (Continued)

Input and Output Capacitors

The LM196 will tolerate a wide range of input and output capacitance, but long wire runs or small values of output capacitance can sometimes cause problems. If an output capacitor is used, it should be 1 μF or larger. We suggest 10 μF solid tantalum if significant improvements in high frequency output impedance are needed (see output impedance graph). This capacitor should be as close to the regulator as possible, with short leads, to reduce the effects of lead inductance. No input capacitor is needed if the regulator is within 6 inches of the power supply filter capacitor, using 18 gauge stranded wire. For longer wire runs, the LM196 input should be bypassed locally with a 4.7 μF (or larger) solid tantalum capacitor, or a 100 μF (or larger) aluminum electrolytic capacitor.

Correcting for Output Wire Losses (LM196/LM396)

Three-terminal regulators can only provide partial Kelvin load sensing (see Load Regulation). Full remote sensing can be added by using an external op amp to cancel the effect of voltage drops in the unsensed positive output lead. In Figure 7, the LM301A op amp forces the voltage loss across the unsensed output lead to appear across R3. The current through R3 then flows out the V^- pin of the op amp through R4. The voltage drop across R4 will raise the output voltage by an amount equal to the line loss, just cancelling the line loss itself. A small (≈ 40 mV) initial output voltage error is created by the quiescent current of the op amp. Cancellation range is limited by the maximum output current of the op amp, about 300 mV as shown. This can be raised by increasing R3 or R4 at the expense of more initial output error.

Transformers and Diodes

Proper transformer ratings are very important in a high current supply because of the conflicting requirements of efficiency and tolerance to low-line conditions. A transformer with a high secondary voltage will waste power and cause unnecessary heating in the regulator. Too low a secondary voltage will cause loss of regulation under low-line conditions. The following formulas may be used to calculate the required secondary voltage and current ratings using a full-wave center tap:

$$V_{\text{rms}} = \left(\frac{V_{\text{OUT}} + V_{\text{REG}} + V_{\text{RECT}} + V_{\text{RIPPLE}}}{\sqrt{2}} \right) \left(\frac{V_{\text{NOM}}}{V_{\text{LOW}}} \right) (1.1)^*$$

$$I_{\text{rms}} = (I_{\text{OUT}}) (1.2) \quad (\text{Full-wave center tap})$$

where:

V_{OUT} = DC regulated output voltage

V_{REG} = Minimum input-output voltage of regulator

V_{RECT} = Rectifier forward voltage drop at three times DC output current

V_{RIPPLE} = 1/2 peak-to-peak capacitor ripple voltage

$$= \frac{(5.3 \times 10^{-3}) (I_{\text{OUT}})}{2C}$$

*The factor of 1.1 is only an approximate factor accounting for load regulation of the transformer.

V_{NOM} = Nominal line voltage AC rms

V_{LOW} = Low line voltage AC rms

I_{OUT} = DC output current

Example: $I_{\text{OUT}} = 10\text{A}$, $V_{\text{OUT}} = 5\text{V}$

Assume: $V_{\text{REG}} = 2.2\text{V}$, $V_{\text{RECT}} = 1.2\text{V}$

$V_{\text{RIPPLE}} = 2 V_{\text{P-P}}$, $V_{\text{NOM}} = 115\text{V}$,

$V_{\text{LOW}} = 105\text{V}$

$$V_{\text{rms}} = \left(\frac{5 + 2.2 + 1.2 + 1}{\sqrt{2}} \right) \left(\frac{115}{105} \right) 1.1$$

$$= 8.01 V_{\text{rms}}$$

$$\text{Capacitor } C = \frac{(5.3 \times 10^{-3}) (I_{\text{OUT}})}{2 \times V_{\text{RIPPLE}}}$$

$$= \frac{(5.3 \times 10^{-3}) (10)}{2} = 26,500 \mu\text{F}$$

The diodes used in a full-wave rectified capacitor input supply must have a DC current rating considerably higher than the average current flowing through them. In a 10A supply, for instance, the average current through each diode is only 5A, but the diodes should have a rating of 10A–15A. There are many reasons for this, both thermal and electrical. The diodes conduct current in pulses about 3.5 ms wide with a peak value of 5–8 times the average value, and an rms value 1.5–2.0 times the average value. This results in long term diode heating roughly equivalent to 10A DC current. The most demanding condition however, may be the one cycle surge through the diode during power turn on. The peak value of the surge is about 10–20 times the DC output current of the supply, or 100A–200A for a 10A supply. The diodes must have a one cycle non-repetitive surge rating of 200A or more, and this is usually not found in a diode with less than 10A average current rating. Keep in mind that even though the LM196 may be used at current levels below 10A, the diodes may still have to survive shorted output conditions where average current could rise to 12A–15A. Smaller transformers and filter capacitors used in lower current supplies will reduce surge currents, but unless specific information is available on worst-case surges, it is best not to economize on diodes. Stud-mounted devices in a DO-4 package are recommended. Cathode-to-case types may be bolted directly to the same heat sink as the LM196 because the case of the regulator is its power input. Part numbers to consider are the 1N1200 series rated at 12A average current in a DO-4 stud package. Additional types include common cathode duals in a TO-3 package, both standard and Schottky, and various duals in plastic filled assemblies. Schottky diodes will improve efficiency, especially in low voltage applications. In a 5V supply for instance, Schottky diodes will decrease wasted power by up to 6W, or alternatively provide an additional 5% "drop out" margin for low-line conditions. Several manufacturers are producing "high efficiency" diodes with a forward voltage drop nearly as good as Schottkys at high current levels. These devices do not have the low breakdown voltages of Schottkys, so are much less prone to reverse breakdown induced failures.

*Regulation can be improved by adding an LM336 reference diode to increase the effective reference voltage to 3.75V. Load and line regulation are improved by 3:1, including thermal effects.

FIGURE 3. Improving Regulation*

TL/H/9059-11

FIGURE 4. Reducing Regulator Power Dissipation

*R3 is selected to supply partial load current. Therefore, a minimum load must always be maintained to prevent the regulated output from rising uncontrolled. R3 must be greater than $(V_{MAX} - V_{OUT})/I_{MIN}$, where V_{MAX} is worst-case high input voltage, and I_{MIN} is the minimum load current. R3 must be rated for at least $(V_{IN} - V_{OUT})^2/R3$ watts. Regulator power dissipation will be reduced by a factor of 2-3 in a typical situation where minimum load current is 1/2 full load current. Regulator dissipation will peak at:

$$V_{IN} = \frac{(R3)(I_{OUT})}{2} + V_{OUT}$$

and will be equal to:

$$P_{MAX} = \frac{(R3)(I_{OUT})^2}{4} \text{ Assuming: } (R3)(I_{OUT}) \leq V_{MAX} - V_{OUT}$$

A few words of caution; (1) R3 power rating must be increased to $(V_{MAX})^2/R3$ if continuous output shorts are possible. (2) Under normal load conditions, system power dissipation is not changed, but under short circuit conditions system power dissipation increases by $(V_{IN})^2/R3$ watts over the already high power of a shorted regulator. The LM196 will not be harmed and neither will R3 if it is rated properly, but the raw supply components must be able to withstand the overload also. Thermal shutdown of the LM196 will probably occur for sustained shorts, somewhat alleviating the problem.

LM317L 3-Terminal Adjustable Regulator

General Description

The LM317L is an adjustable 3-terminal positive voltage regulator capable of supplying 100 mA over a 1.2V to 37V output range. It is exceptionally easy to use and requires only two external resistors to set the output voltage. Further, both line and load regulation are better than standard fixed regulators. Also, the LM317L is available packaged in a standard TO-92 transistor package which is easy to use.

In addition to higher performance than fixed regulators, the LM317L offers full overload protection. Included on the chip are current limit, thermal overload protection and safe area protection. All overload protection circuitry remains fully functional even if the adjustment terminal is disconnected.

Features

- Adjustable output down to 1.2V
- Guaranteed 100 mA output current
- Line regulation typically 0.01%V
- Load regulation typically 0.1%
- Current limit constant with temperature
- Eliminates the need to stock many voltages
- Standard 3-lead transistor package
- 80 dB ripple rejection
- Output is short circuit protected

Normally, no capacitors are needed unless the device is situated more than 6 inches from the input filter capacitors in which case an input bypass is needed. An optional output capacitor can be added to improve transient response. The adjustment terminal can be bypassed to achieve very high ripple rejection ratios which are difficult to achieve with standard 3-terminal regulators.

Besides replacing fixed regulators, the LM317L is useful in a wide variety of other applications. Since the regulator is "floating" and sees only the input-to-output differential voltage, supplies of several hundred volts can be regulated as long as the maximum input-to-output differential is not exceeded.

Also, it makes an especially simple adjustable switching regulator, a programmable output regulator, or by connecting a fixed resistor between the adjustment and output, the LM317L can be used as a precision current regulator. Supplies with electronic shutdown can be achieved by clamping the adjustment terminal to ground which programs the output to 1.2V where most loads draw little current.

The LM317L is available in a standard TO-92 transistor package and the SO-8 package. The LM317L is rated for operation over a -25°C to 125°C range.

Thermal Rating of SO Package			165		$^{\circ}\text{C/W}$

Note 1: Unless otherwise noted, these specifications apply: $-25^{\circ}\text{C} \leq T_j \leq 125^{\circ}\text{C}$ for the LM317L; $V_{\text{IN}} - V_{\text{OUT}} = 5\text{V}$ and $I_{\text{OUT}} = 40\text{ mA}$. Although power dissipation is internally limited, these specifications are applicable for power dissipations up to 625 mW. I_{MAX} is 100 mA.

Note 2: Regulation is measured at constant junction temperature, using pulse testing with a low duty cycle. Changes in output voltage due to heating effects are covered under the specification for thermal regulation.

Note 3: Thermal resistance of the TO-92 package is 180°C/W junction to ambient with 0.4" leads from a PC board and 160°C/W junction to ambient with 0.125" lead length to PC board.

Typical Performance Characteristics (Output capacitor = 0 μ F unless otherwise noted.)

TL/H/9064-6

Application Hints

In operation, the LM317L develops a nominal 1.25V reference voltage, V_{REF} , between the output and adjustment terminal. The reference voltage is impressed across program resistor R_1 and, since the voltage is constant, a constant current I_1 then flows through the output set resistor R_2 , giving an output voltage of

$$V_{OUT} = V_{REF} \left(1 + \frac{R_2}{R_1} \right) + I_{ADJ}(R_2)$$

Since the 100 μ A current from the adjustment terminal represents an error term, the LM317L was designed to minimize I_{ADJ} and make it very constant with line and load changes. To do this, all quiescent operating current is returned to the output establishing a minimum load current requirement. If there is insufficient load on the output, the output will rise.

FIGURE 1

TL/H/9064-7

External Capacitors

An input bypass capacitor is recommended in case the regulator is more than 6 inches away from the usual large filter capacitor. A 0.1 μ F disc or 1 μ F solid tantalum on the input is suitable input bypassing for almost all applications. The device is more sensitive to the absence of input bypassing when adjustment or output capacitors are used, but the above values will eliminate the possibility of problems.

The adjustment terminal can be bypassed to ground on the LM317L to improve ripple rejection and noise. This bypass capacitor prevents ripple and noise from being amplified as the output voltage is increased. With a 10 μ F bypass capacitor 80 dB ripple rejection is obtainable at any output level. Increases over 10 μ F do not appreciably improve the ripple rejection at frequencies above 120 Hz. If the bypass capacitor is used, it is sometimes necessary to include protection diodes to prevent the capacitor from discharging through internal low current paths and damaging the device.

In general, the best type of capacitors to use is solid tantalum. *Solid tantalum capacitors have low impedance even at high frequencies.* Depending upon capacitor construction, it takes about 25 μ F in aluminum electrolytic to equal 1 μ F solid tantalum at high frequencies. Ceramic capacitors are also good at high frequencies; but some types have a large decrease in capacitance at frequencies around 0.5 MHz. For this reason, a 0.01 μ F disc may seem to work better than a 0.1 μ F disc as a bypass.

Although the LM317L is stable with no output capacitors, like any feedback circuit, certain values of external capacitance can cause excessive ringing. This occurs with values between 500 pF and 5000 pF. A 1 μ F solid tantalum (or 25 μ F aluminum electrolytic) on the output swamps this effect and insures stability.

Load Regulation

The LM317L is capable of providing extremely good load regulation but a few precautions are needed to obtain maximum performance. The current set resistor connected between the adjustment terminal and the output terminal (usually 240 Ω) should be tied directly to the output of the regulator rather than near the load. This eliminates line drops from appearing effectively in series with the reference and degrading regulation. For example, a 15V regulator with 0.05 Ω resistance between the regulator and load will have a load regulation due to line resistance of $0.05\Omega \times I_L$. If the set resistor is connected near the load the effective line resistance will be $0.05\Omega (1 + R_2/R_1)$ or in this case, 11.5 times worse.

Figure 2 shows the effect of resistance between the regulator and 240 Ω set resistor.

With the TO-92 package, it is easy to minimize the resistance from the case to the set resistor, by using two separate leads to the output pin. The ground of R_2 can be returned near the ground of the load to provide remote ground sensing and improve load regulation.

FIGURE 2. Regulator with Line Resistance in Output Lead

TL/H/9064-8

Application Hints (Continued)

Thermal Regulation

When power is dissipated in an IC, a temperature gradient occurs across the IC chip affecting the individual IC circuit components. With an IC regulator, this gradient can be especially severe since power dissipation is large. Thermal regulation is the effect of these temperature gradients on output voltage (in percentage output change) per watt of power change in a specified time. Thermal regulation error is independent of electrical regulation or temperature coefficient, and occurs within 5 ms to 50 ms after a change in power dissipation. Thermal regulation depends on IC layout as well as electrical design. The thermal regulation of a voltage regulator is defined as the percentage change of V_{OUT} , per watt, within the first 10 ms after a step of power is applied. The LM317L specification is 0.2%/W, maximum.

In the Thermal Regulation curve at the bottom of the Typical Performance Characteristics page, a typical LM317L's output changes only 7 mV (or 0.07% of $V_{OUT} = -10V$) when a 1W pulse is applied for 10 ms. This performance is thus well inside the specification limit of $0.2\%/W \times 1W = 0.2\%$ maximum. When the 1W pulse is ended, the thermal regulation again shows a 7 mV change as the gradients across the LM317L chip die out. Note that the load regulation error of about 14 mV (0.14%) is additional to the thermal regulation error.

Protection Diodes

When external capacitors are used with *any* IC regulator it is sometimes necessary to add protection diodes to pre-

vent the capacitors from discharging through low current points into the regulator. Most 10 μF capacitors have low enough internal series resistance to deliver 20A spikes when shorted. Although the surge is short, there is enough energy to damage parts of the IC.

When an output capacitor is connected to a regulator and the input is shorted, the output capacitor will discharge into the output of the regulator. The discharge current depends on the value of the capacitor, the output voltage of the regulator, and the rate of decrease of V_{IN} . In the LM317L, this discharge path is through a large junction that is able to sustain a 2A surge with no problem. This is not true of other types of positive regulators. For output capacitors of 25 μF or less, the LM317L's ballast resistors and output structure limit the peak current to a low enough level so that there is no need to use a protection diode.

The bypass capacitor on the adjustment terminal can discharge through a low current junction. Discharge occurs when *either* the input or output is shorted. Internal to the LM317L is a 50 Ω resistor which limits the peak discharge current. No protection is needed for output voltages of 25V or less and 10 μF capacitance. Figure 3 shows an LM317L with protection diodes included for use with outputs greater than 25V and high values of output capacitance.

LM320L 3-Terminal Negative Regulators

General Description

The LM320L series of 3-terminal negative voltage regulators features fixed output voltages of $-5V$, $-12V$, and $-15V$, with output current capabilities in excess of 100 mA. These devices were designed using the latest computer techniques for optimizing the packaged IC thermal/electrical performance. The LM320L series, even when combined with a minimum output compensation capacitor of $0.1 \mu F$, exhibits an excellent transient response, a maximum line regulation of $0.07\% V_O/V$, and a maximum load regulation of $0.01\% V_O/mA$.

The LM320L series also includes, as self-protection circuitry: safe operating area circuitry for output transistor power dissipation limiting, a temperature independent short circuit current limit for peak output current limiting, and a thermal shutdown circuit to prevent excessive junction temperature. Although designed primarily as fixed voltage regulators, these devices may be combined with simple external circuitry for boosted and/or adjustable voltages and currents. The LM320L series is available in the 3-lead TO-92 package.

For output voltages other than $-5V$, $-12V$ and $-15V$, the LM137 series provides an output voltage range from $-1.2V$ to $-47V$.

Features

- Preset output voltage error is less than $\pm 5\%$ over load, line and temperature
- LM320L is specified at an output current of 100 mA
- Internal short-circuit, thermal and safe operating area protection
- Easily adjustable to higher output voltages
- Maximum line regulation less than $0.07\% V_{OUT}/V$
- Maximum load regulation less than $0.01\% V_{OUT}/mA$
- Easily compensated with a small $0.1 \mu F$ output capacitor

LM330 3-Terminal Positive Regulator

General Description

The LM330 5V 3-terminal positive voltage regulator features an ability to source 150 mA of output current with an input-output differential of 0.6V or less. Familiar regulator features such as current limit and thermal overload protection are also provided.

The low dropout voltage makes the LM330 useful for certain battery applications since this feature allows a longer battery discharge before the output falls out of regulation. For example, a battery supplying the regulator input voltage may discharge to 5.6V and still properly regulate the system and load voltage. Supporting this feature, the LM330 protects both itself and regulated systems from negative voltage inputs resulting from reverse installations of batteries.

Other protection features include line transient protection up to 26V, when the output actually shuts down to avoid damaging internal and external circuits. Also, the LM330 regulator cannot be harmed by a temporary mirror-image insertion.

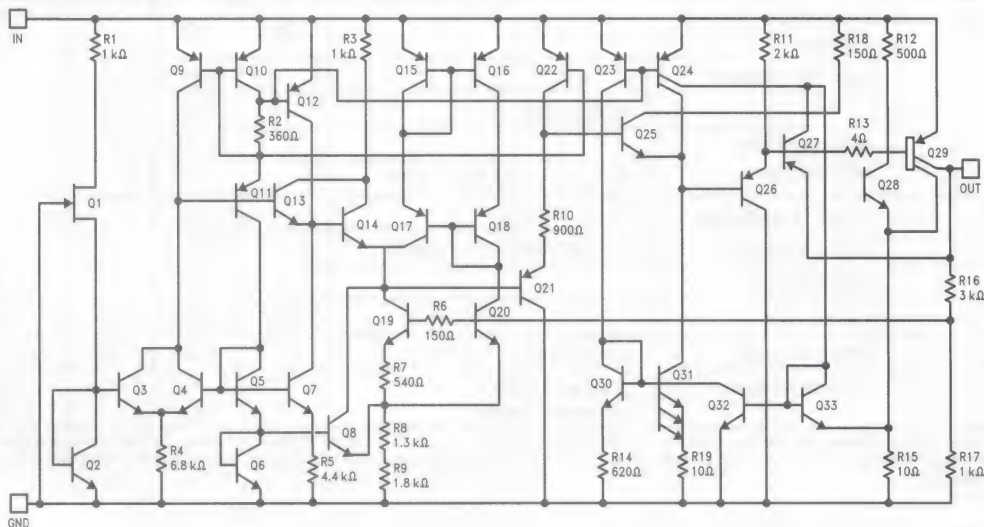

Features

- Input-output differential less than 0.6V
- Output current of 150 mA
- Reverse battery protection
- Line transient protection
- Internal short circuit current limit
- Internal thermal overload protection
- Mirror-image insertion protection
- 100% electrical burn-in in the thermal limit

Output voltage changes due to changes in internal temperature must be taken into account separately.

Typical Performance Characteristics

Typical Performance Characteristics (Continued)

TL/H/9306-4

Typical Applications

The LM330 is designed specifically to operate at lower input to output voltages. The device is designed utilizing a power lateral PNP transistor which reduces dropout voltage from 2.0V to 0.3V when compared to IC regulators using NPN pass transistors. Since the LM330 can operate at a much lower input voltage, the device power dissipation is reduced, heat sinking can be simpler and device reliability im-

proved through lower chip operating temperature. Also, a cost savings can be utilized through use of lower power/voltage components. In applications utilizing battery power, the LM330 allows the battery voltage to drop to within 0.3V of output voltage prior to the voltage regulator dropping out of regulation.

TL/H/9306-5

* Required if regulator is located far from power supply filter.

** C2 may be either an Aluminum or Tantalum type capacitor but must be rated to operate at -40°C to guarantee regulator stability to that temperature extreme. $10 \mu\text{F}$ is the minimum value required for stability and may be increased without bound. Locate as close as possible to the regulation.

TL/H/9306-6

Note: Compared to IC regulator with 2.0V dropout voltage and $I_{Omax} = 6.0 \text{ mA}$.

Definition of Terms

Dropout Voltage: The input-output voltage differential at which the circuit ceases to regulate against further reduction in input voltage. Measured when the output voltage has dropped 100 mV from the nominal value obtained at 14V input, dropout voltage is dependent upon load current and junction temperature.

Input Voltage: The DC voltage applied to the input terminals with respect to ground.

Input-Output Differential: The voltage difference between the unregulated input voltage and the regulated output voltage for which the regulator will operate.

Line Regulation: The change in output voltage for a change in the input voltage. The measurement is made under conditions of low dissipation or by using pulse techniques such that the average chip temperature is not significantly affected.

Load Regulation: The change in output voltage for a change in load current at constant chip temperature.

Long Term Stability: Output voltage stability under accelerated life-test conditions after 1000 hours with maximum rated voltage and junction temperature.

Output Noise Voltage: The rms AC voltage at the output, with constant load and no input ripple, measured over a specified frequency range.

Quiescent Current: That part of the positive input current that does not contribute to the positive load current. The regulator ground lead current.

Ripple Rejection: The ratio of the peak-to-peak input ripple voltage to the peak-to-peak output ripple voltage.

Temperature Stability of V_o : The percentage change in output voltage for a thermal variation from room temperature to either temperature extreme.

LM337L 3-Terminal Adjustable Regulator

General Description

The LM337L is an adjustable 3-terminal negative voltage regulator capable of supplying 100 mA over a 1.2V to 37V output range. It is exceptionally easy to use and requires only two external resistors to set the output voltage. Furthermore, both line and load regulation are better than standard fixed regulators. Also, the LM337L is packaged in a standard TO-92 transistor package which is easy to use.

In addition to higher performance than fixed regulators, the LM337L offers full overload protection. Included on the chip are current limit, thermal overload protection and safe area protection. All overload protection circuitry remains fully functional even if the adjustment terminal is disconnected.

Normally, only a single 1 μ F solid tantalum output capacitor is needed unless the device is situated more than 6 inches from the input filter capacitors, in which case an input bypass is needed. A larger output capacitor can be added to improve transient response. The adjustment terminal can be bypassed to achieve very high ripple rejection ratios which are difficult to achieve with standard 3-terminal regulators.

Besides replacing fixed regulators, the LM337L is useful in a wide variety of other applications. Since the regulator is "floating" and sees only the input-to-output differential voltage, supplies of several hundred volts can be regulated as long as the maximum input-to-output differential is not exceeded.

Also, it makes an especially simple adjustable switching regulator, a programmable output regulator, or by connecting a fixed resistor between the adjustment and output, the LM337L can be used as a precision current regulator. Supplies with electronic shutdown can be achieved by clamping the adjustment terminal to ground which programs the output to 1.2V where most loads draw little current.

The LM337L is available in a standard TO-92 transistor package and a SO-8 surface mount package. The LM337L is rated for operation over a -25°C to $+125^{\circ}\text{C}$ range.

For applications requiring greater output current in excess of 0.5A and 1.5A, see LM137 series data sheets. For the positive complement, see series LM117 and LM317L data sheets.

Features

- Adjustable output down to 1.2V
- Guaranteed 100 mA output current
- Line regulation typically 0.01%/V
- Load regulation typically 0.1%
- Current limit constant with temperature
- Eliminates the need to stock many voltages
- Standard 3-lead transistor package
- 80 dB ripple rejection
- Output is short circuit protected

Connection Diagram

Order Number LM337LM or LM337LZ
See NS Package Number M08A or Z03A

Typical Applications

1.2V–25V Adjustable Regulator

Full output current not available at high input-output voltages

$$-V_{OUT} = -1.25V \left(1 + \frac{R2}{240\Omega} \right)$$

*C1 = 1 μ F solid tantalum or 10 μ F aluminum electrolytic required for stability

*C2 = 1 μ F solid tantalum is required only if regulator is more than 4" from power supply filter capacitor

Regulator with Trimmable Output Voltage

Trim Procedure:

- If V_{OUT} is -23.08V or bigger, cut out R3 (if smaller, don't cut it out).
- Then if V_{OUT} is -22.47V or bigger, cut out R4 (if smaller, don't).
- Then if V_{OUT} is -22.16V or bigger, cut out R5 (if smaller, don't).

This will trim the output to well within 1% of -22.00V_{DC} , without any of the expense or trouble of a trim pot (see LB-46). Of course, this technique can be used at any output voltage level.

Absolute Maximum Ratings

Ripple Rejection Ratio	$V_{\text{OUT}} = -10\text{V}$, $F = 120\text{Hz}$, $C_{\text{ADJ}} = 0$ $C_{\text{ADJ}} = 10\mu\text{F}$	66	65 80		 dB dB
Long-Term Stability	$T_A = 125^{\circ}\text{C}$		0.3	1	%

Note 1: Unless otherwise specified, these specifications apply $-25^{\circ}\text{C} \leq T_J \leq +125^{\circ}\text{C}$ for the LM337L; $|V_{\text{IN}} - V_{\text{OUT}}| = 5\text{V}$ and $I_{\text{OUT}} = 40\text{mA}$. Although power dissipation is internally limited, these specifications are applicable for power dissipations up to 625 mW. I_{MAX} is 100 mA.

Note 2: Regulation is measured at constant junction temperature, using pulse testing with a low duty cycle. Changes in output voltage due to heating effects are covered under the specification for thermal regulation.

Note 3: Thermal resistance of the TO-92 package is 180°C/W junction to ambient with 0.4" leads from a PC board and 160°C/W junction to ambient with 0.125" lead length to PC board.

LM723/LM723C Voltage Regulator

General Description

The LM723/LM723C is a voltage regulator designed primarily for series regulator applications. By itself, it will supply output currents up to 150 mA; but external transistors can be added to provide any desired load current. The circuit features extremely low standby current drain, and provision is made for either linear or foldback current limiting.

The LM723/LM723C is also useful in a wide range of other applications such as a shunt regulator, a current regulator or a temperature controller.

The LM723C is identical to the LM723 except that the LM723C has its performance guaranteed over a 0°C to +70°C temperature range, instead of -55°C to +125°C.

Features

- 150 mA output current without external pass transistor
- Output currents in excess of 10A possible by adding external transistors
- Input voltage 40V max
- Output voltage adjustable from 2V to 37V
- Can be used as either a linear or a switching regulator

Note 1: See derating curves for maximum power rating above 25°C .

Note 2: Unless otherwise specified, $T_A = 25^\circ\text{C}$, $V_{IN} = V^+ = V_C = 12\text{V}$, $V^- = 0$, $V_{OUT} = 5\text{V}$, $I_L = 1\text{ mA}$, $R_{SC} = 0$, $C_1 = 100\text{ pF}$, $C_{REF} = 0$ and divider impedance as seen by error amplifier $\leq 10\text{ k}\Omega$ connected as shown in Figure 1. Line and load regulation specifications are given for the condition of constant chip temperature. Temperature drifts must be taken into account separately for high dissipation conditions.

Note 3: L_1 is 40 turns of No. 20 enameled copper wire wound on Ferroxcube P36/22-3B7 pot core or equivalent with 0.009 in. air gap.

Note 4: Figures in parentheses may be used if R1/R2 divider is placed on opposite input of error amp.

Note 5: Replace R1/R2 in figures with divider shown in Figure 13.

Note 6: V^+ must be connected to a +3V or greater supply.

Note 7: For metal can applications where V_Z is required, an external 6.2V zener diode should be connected in series with V_{OUT} .

Note 8: Guaranteed by correlation to other tests.

Note 9: Refer to RETS723X military specifications for the LM723.

LM1578/LM2578/LM3578 Switching Regulator

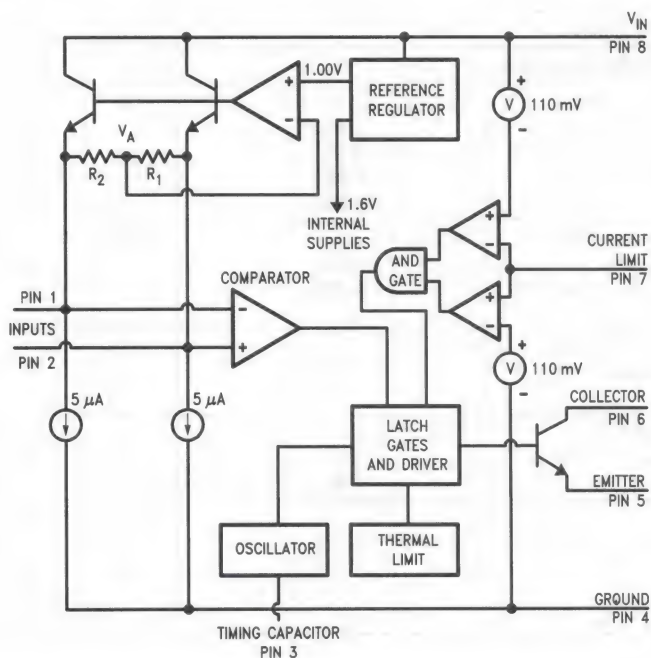

General Description

The LM1578 is a flexible 8-pin switching regulator which can easily be set up for such dc-to-dc voltage conversion circuits as the buck, boost, and inverting configurations. The LM1578 features a unique comparator input stage which not only has separate pin-outs for both the inverting and non-inverting inputs, but also provides an internal 1.0V reference to each input, thereby simplifying circuit design and p.c. board layout. The output can switch up to 750 mA and has output pins for its collector and emitter to promote design flexibility. The current limit terminal may be referenced to either the ground or the V_{IN} terminal, depending upon the application. In addition, the LM1578 has an on-board oscillator, which is set by a single external capacitor.

Features

- Inverting and non-inverting inputs
- 1.0V reference at inputs
- Operates from supply voltages of 2V to 40V
- Output current up to 750 mA, saturation less than 1V
- Oscillator frequency adjustable to 100 kHz
- Current limit and thermal shut down
- Duty cycle up to 90%
- Design flexibility including buck, boost, inverting, and transformer configurations

	Output On, I _c = 750 mA	14			14			

Note 1: Absolute Maximum Ratings indicate limits beyond which damage to the device may occur. DC and AC electrical specifications do not apply when operating the device beyond its Rated Operating Conditions.

Note 2: At elevated temperatures, devices must be derated based on package thermal resistance. The device in a TO-5 package must be derated at 150°C/W, junction to ambient or 45°C/W, junction to case. The thermal resistance for the 8-pin N package is 130°C/W, junction to ambient.

Note 3: Unless otherwise specified, these specifications apply for $V_{in} = 2$ V (2.2V, < -25°C) and $V_{in} = 40$ V. Timing Capacitor = 4000 pF with 25% and 75% duty cycle. Normal typeface indicates $T_J = 25^\circ\text{C}$ limits. **Boldface type indicates limits for full temperature range.** This is $T_J = -55^\circ\text{C}$ to $+150^\circ\text{C}$ for the LM1578, $T_J = -40^\circ\text{C}$ to $+125^\circ\text{C}$ for the LM2578, and $T_J = 0^\circ\text{C}$ to $+125^\circ\text{C}$ for the LM3578.

Note 4: I_1 and I_2 are the external sink currents at the inputs.

Note 5: Guaranteed and 100% production tested.

Note 6: Guaranteed (but not 100% production tested) over the operating temperature ranges. These limits are not to be used to calculate outgoing quality levels.

Note 7: Connection of a 10 k Ω resistor from pin 1 to pin 4 establishes the duty cycle at its maximum of 90% with a maximum voltage swing on the output collector of 40V. Applying the minimum current sense voltage will not reduce the duty cycle to less than 50%. Applying the maximum current limit sense voltage is certain to reduce the duty cycle below 50%. An additional 15 mV above the sense voltage may be required to reduce the duty cycle to 0% (see current limit of the typical performance characteristics).

Note 8: Input terminals are protected from accidental shorts to ground but if external voltages higher than the reference voltage is applied, excessive current will flow and should be limited to less than 5 mA.

Test Circuit*

Parameter tests can be made using the test circuit shown. Select the desired V_{in} , collector voltage and duty cycle with adjustable power supplies. A digital volt meter with an input resistance greater than 100 M Ω should be used to measure the following:

Input Reference Voltage to Ground; S1 in either position.

Level Shift Accuracy (%) = $(T_{P3}(V)/1V) \times 100\%$; S1 at $I_1 = I_2 = 1 \text{ mA}$

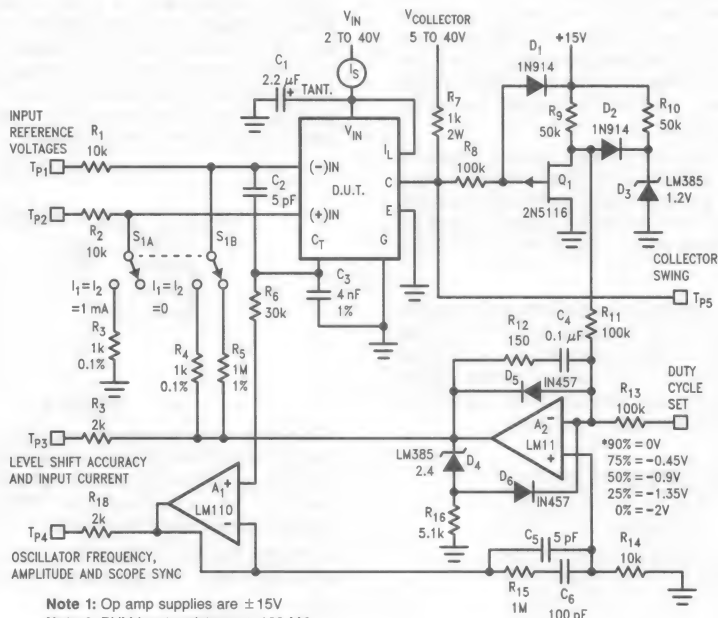

Input Current (mA) = $(1V - T_{P3}(V))/1 \text{ M}\Omega$; S1 at $I_1 = I_2 = 0 \text{ mA}$.

Oscillator T_{P4} can be measured using a frequency counter or an oscilloscope.

The current limit sense voltage is measured by connecting an adjustable 0 to 1V floating power supply in series with the current limit terminal and referring it to either the ground or the V_{in} terminal. Set the duty cycle to 90% and monitor test point T_{P5} while adjusting the floating power supply voltage until the LM1578's duty cycle just reaches 0%. This voltage is the current limit sense voltage.

The supply current should be measured with the duty cycle at 0% and S1 in the $I_1 = I_2 = 0 \text{ mA}$ position.

*LM1578 specifications are measured using automated test equipment. This circuit is provided for the customer's convenience when checking parameters. Due to possible variations in testing conditions, the measured values from these testing procedures may not match those of the factory.

TL/H/8711-3

Definition of Terms

Input Reference Voltage: The reference voltage referred to ground, applied to either the inverting or non-inverting inputs, which will cause the output to switch on or off.

Input Reference Current: The current applied to either the inverting or the non-inverting input which will cause the output to switch on or off.

Input Level Shift Accuracy: For two equal resistors sinking current from the inverting and non-inverting input terminals, the input level shift accuracy is the ratio of the voltage across the resistors to produce a given duty cycle at the output.

Collector Saturation Voltage: With the inverting input terminal grounded thru a 10 k Ω resistor and the output transistor's emitter connected to ground, the collector saturation

voltage is the collector-to-emitter voltage for a given collector current.

Emitter Saturation Voltage: With the inverting input terminal grounded thru a 10 k Ω resistor and the output transistor's collector connected to V_{in} , the emitter saturation voltage is the collector-to-emitter voltage for a given emitter current.

Current Limit Sense Voltage: The voltage referred to either the supply or the ground terminal which will cause the output transistor to turn off and resets cycle-by-cycle at the oscillator frequency.

Current Limit Sense Current: The bias current for the current limit terminal at sense voltage.

Supply Current: The IC power supply current, excluding the output transistor's collector current, with the oscillator operating.

Functional Description

The LM1578 is a very simple device. A control signal is fed back to the LM1578's comparator section for output error detection. The comparator and oscillator feed their respective signals to a logic network for determining when the output transistor is to be turned on and off. The following is a brief description of the various stages of the LM1578.

COMPARATOR INPUT STAGE

The LM1578 has a unique comparator input stage—not only are both the inverting and non-inverting inputs available to the user, but both are referenced to a 1.0V reference. This is accomplished as follows: A 1.0V reference is fed into a modified voltage follower circuit (see FUNCTIONAL DIAGRAM). When both inputs are floating, no current flows through either R_1 or R_2 , and thus, both inputs to the comparator are at the same potential as V_a , i.e. 1.0V. When one input, say the non-inverting input, is moved ΔV away from V_a , a current of $\Delta V/R_1$ flows through R_1 . This same current flows through R_2 and thus the comparator sees a total voltage difference of $2 \Delta V$ between its inputs. The high gain of the system immediately corrects for this imbalance and returns both inputs to the 1.0V level.

The LM1578's unique comparator input stage increases circuit flexibility, while minimizing the total number of parts. The inverting switching regulator configuration, for example, can be set-up without having to use an external op amp for feedback polarity reversal (See TYPICAL APPLICATIONS).

OSCILLATOR

The LM1578 provides an on-board oscillator which can be adjusted up to 100 kHz. Its frequency is set by a single external capacitor, C_1 . A graph displaying C_1 versus frequency is shown in Figure 1. The oscillator provides a blanking pulse to turn off the output transistor for at least 10% of each oscillator cycle to help protect the device.

FIGURE 1

TL/H/8711-4

OUTPUT TRANSISTOR

The output transistor is capable of delivering up to 750 mA of current with a saturation voltage of less than 1.2V. The collector and emitter are both available as shown in the functional diagram.

CURRENT LIMIT

The LM1578's current limit is novel in that it may be referenced to either the ground or the V_{in} terminal, and operates on a cycle-by-cycle basis.

The current limit section consists of two comparators: one with its non-inverting input referenced to a voltage, V , 110 mV below V_{in} , the other with its inverting input refer-

enced 110 mV above ground (see FUNCTIONAL DIAGRAM). The current limit is activated whenever the current limit terminal is pulled 110 mV away from either V_{in} or ground.

Typical Applications

The LM1578 may be operated in either the continuous or the discontinuous conduction mode. The following applications (except for the Buck-Boost Regulator) are designed for continuous conduction operation. That is, the inductor current is not allowed to fall to zero. This mode of operation has higher efficiency and lower EMI characteristics than the discontinuous mode.

BUCK REGULATOR

The buck configuration is used to step an input voltage down to a lower level. Transistor Q1 in Figure 2 chops the input D.C. voltage into a squarewave. This squarewave is then converted back into a D.C. voltage of lower magnitude by the low pass filter consisting of L1 and C1. The duty cycle, D, of the squarewave relates the output voltage to the input voltage by the following relation:

$$V_{out} = D \times V_{in} = V_{in} \times (t_{on}) / (t_{on} + t_{off})$$

TL/H/8711-5

FIGURE 2

Figure 3 is a 15V to 5V buck regulator with an output current, I_o , of 350 mA. The circuit becomes discontinuous at 20% of $I_o(\max)$, has 10 mV of output voltage ripple, an efficiency of 75%, a load regulation of 30 mV (70 mA to 350 mA) and a line regulation of 10 mV ($12 \leq V_{in} \leq 18V$).

Component values are selected as follows:

$$R1 = (V_o - 1) \times R2 \text{ where } R2 = 10 \text{ k}\Omega$$

$$R3 = V / I_{sw}(\max)$$

$$R3 = 0.15 \Omega$$

where:

V is the current limit sense voltage, 0.11V

$I_{sw}(\max)$ is the maximum allowable current thru the output transistor.

L1 is the inductor and may be found from the inductance calculation chart, as follows.

Given $V_{in} = 15V$

$V_o = 5V$

$I_o(\max) = 350 \text{ mA}$

$f_{osc} = 50 \text{ kHz}$

Discontinuous at 20% of $I_o(\max)$.

Note that since the circuit will become discontinuous at 20% of $I_o(\max)$, the load current must not be allowed to fall below 70 mA.

Step 1: Calculate the maximum D.C. current through the inductor, $I_{IND}(\max)$. The necessary equations are indicated at the top of the chart and show that $I_{IND}(\max) = I_o(\max)$ for the buck configuration. Thus, $I_{IND}(\max) = 350 \text{ mA}$.

Typical Applications (Continued)

Step 2: Calculate the inductor Volts-sec product, $E \cdot T_{OP}$, according to the equations given from the chart. For the Buck;

$$\begin{aligned} E \cdot T_{OP} &= (V_{IN} - V_O) (V_O/V_{IN}) (1000/f_{OSC}) \\ &= (15 - 5) (5/15) (1000/50) \\ &= 100V - \mu s. \end{aligned}$$

with the oscillator frequency, f_{OSC} , expressed in kHz.

$V_{IN} = 15V$
 $V_O = 5V$
 $V_{ripple} = 50 mV$
 $I_O = 350 mA$
 $f_{OSC} = 50 kHz$
 $R1 = 40 k\Omega$
 $R2 = 10 k\Omega$
 $R3 = 0.15 \Omega$
 $C1 = 1820 pF$
 $C2 = 220 \mu F$
 $C3 = 20 pF$
 $L1 = 470 \mu H$
 $D1 = 1N5818$

TL/H/8711-6

FIGURE 3. Buck or Step-Down Regulator

Step 3: Using the graph with axis labeled "Discontinuous At % I_O " and " $I_{IND(max, DC)}$ " find the point where the desired maximum inductor current, $I_{IND(max, DC)}$ intercepts the desired discontinuity percentage.

In this example, the point of interest is where the 0.35A line intersects with the 20% line. This is nearly the midpoint of the horizontal axis.

Step 4: This last step is merely the translation of the point found in Step 3 to the graph directly below it. This is accomplished by moving straight down the page to the point which intercepts the desired $E \cdot T_{OP}$. For this example, $E \cdot T_{OP}$ is 66V- μs and the desired inductor value is 470 μH . Since this example was for 20% discontinuity, the bottom chart could have been used directly, as noted in step 3 of the chart instructions.

For a full line of standard inductor values, contact Pulse Engineering (San Diego, Calif.) regarding their PE526XX series, or A. I. E. Magnetics (Nashville, Tenn.).

A more precise inductance value may be calculated for the Buck, Boost and Inverting Regulators as follows:

BUCK

$$L = V_O (V_{IN} - V_O) / (\Delta I_O V_{IN} f_{OSC})$$

BOOST

$$L = V_{IN}^2 (V_O - V_{IN}) / (\Delta I_O f_{OSC} V_O^2)$$

INVERT

$$L = V_{IN}^2 |V_O| / [\Delta I_O (V_{IN} + |V_O|) f_{OSC}]$$

where:

$\Delta I_O = 2I_O \times (\text{Discontinuity Factor})$. The Discontinuity Factor is the percent discontinuity of I_O expressed as a decimal (i.e.; for 10% discontinuity, the discontinuity factor is 0.1).

$C1$ is the frequency selection capacitor found in Figure 1.

$$C2 \geq V_O (V_{IN} - V_O) / (8f_{OSC}^2 V_{IN} V_{ripple} L1)$$

where V_{ripple} is the peak-to-peak output voltage ripple.

$C3$ is necessary for continuous operation and is generally in the 10 to 30 pF range.

$D1$ should be a Schottky type diode, such as the 1N5818 or 1N5819.

BUCK WITH BOOSTED OUTPUT CURRENT

For applications requiring a large output current, an external transistor may be used as shown in Figure 4. This circuit steps a 15V supply down to 5V with 1.5A of output current. The output ripple is 50 mV, with an efficiency of 80%, a load regulation of 40 mV (150 mA to 1.5A), and a line regulation of 20 mV ($12V \leq V_{IN} \leq 18V$).

Component values are selected as outlined for the buck regulator with a discontinuity factor of 10%, with the addition of $R4$ and $R5$:

$$R4 = 10V_{BE1}B_f/I_P$$

$$R5 = (V_{IN} - V - V_{BE1} - V_{sat}) B_f / (I_{IND(max, DC)} + I_{R4})$$

where:

V_{BE1} is the V_{BE} of transistor Q1.

V_{sat} is the saturation voltage of the LM1578 output transistor.

V is the current limit sense voltage.

B_f is the forced current gain of transistor Q1 ($B_f = 30$ for Figure 4).

$$I_{R4} = V_{BE1}/R4$$

$$I_P = I_{IND(max, DC)} + 0.5\Delta I_O$$

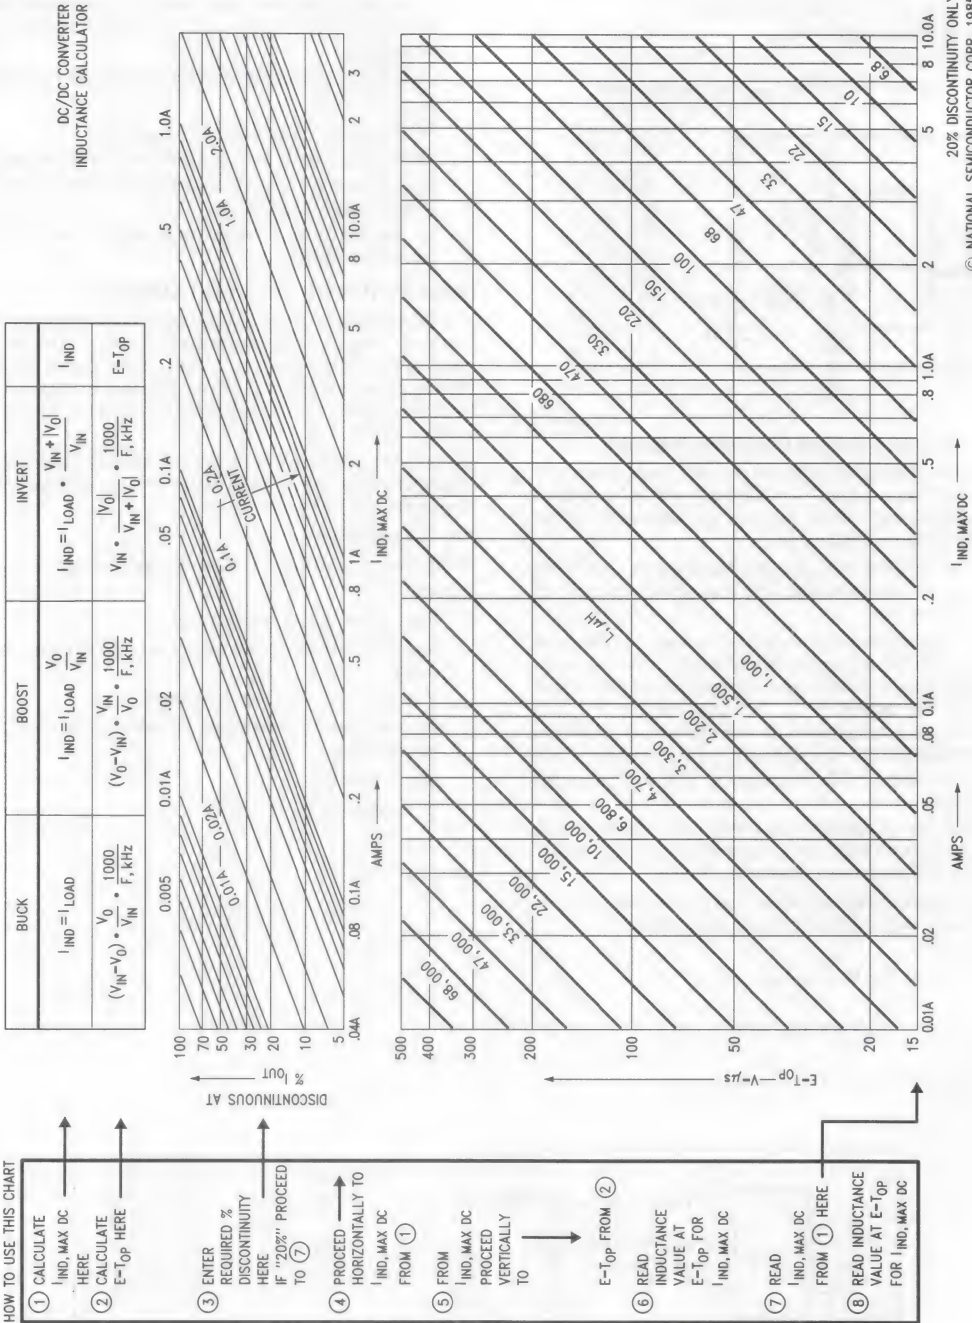

$V_{IN} = 15V$
 $V_O = 5V$
 $V_{ripple} = 50 mV$
 $I_O = 1.5A$
 $f_{OSC} = 50 kHz$
 $R1 = 40 k\Omega$
 $R2 = 10 k\Omega$
 $R3 = 0.05 \Omega$
 $R4 = 200 \Omega$
 $R5 = 330 \Omega$
 $C1 = 1820 pF$
 $C2 = 330 \mu F$
 $C3 = 20 pF$
 $L1 = 220 \mu H$
 $D1 = 1N5819$
 $Q1 = D45$

TL/H/8711-8

FIGURE 4. Buck Converter with Boosted Output Current

Typical Applications (Continued)

Typical Applications (Continued)

BOOST REGULATOR

The boost regulator converts a low input voltage into a higher output voltage. The basic configuration is shown in *Figure 5*. Energy is stored in the inductor while the transistor is on and then transferred with the input voltage to the output capacitor for filtering when the transistor is off. Thus,

$$V_o = V_{in} + V_{in}(t_{on}/t_{off}).$$

TL/H/8711-9

FIGURE 5

The circuit of *Figure 6* converts a 5V supply into a 15V supply with 150 mA of output current, a load regulation of 14 mV (30 mA to 150 mA), and a line regulation of 35 mV ($4.5V \leq V_{in} \leq 8.5V$).

$V_{in} = 5V$
 $V_o = 15V$
 $V_{ripple} = 10\text{ mV}$
 $I_o = 150\text{ mA}$
 $f_{osc} = 50\text{ kHz}$
 $R1 = 140\text{ k}\Omega$
 $R2 = 10\text{ k}\Omega$
 $R3 = 0.1\text{ }\Omega$
 $R4 = 220\text{ k}\Omega$
 $C1 = 1820\text{ pF}$
 $C2 = 470\text{ }\mu\text{F}$
 $C3 = 20\text{ pF}$
 $C4 = 0.0022\text{ }\mu\text{F}$
 $L1 = 330\text{ }\mu\text{H}$
 $D1 = 1N5818$

TL/H/8711-11

FIGURE 6. Boost or Step-Up Regulator

$$R1 = (V_o - 1) R2 \text{ where } R2 = 10\text{ k}\Omega.$$

$$R3 = V/(I_{IND}(\text{max}, \text{DC}) + 0.5 \Delta I_o)$$

where:

ΔI_o is defined in the "Buck Regulator" section.

R4, C3 and C4 are necessary for continuous operation and are typically 220 k Ω , 20 pF, and 0.0022 μF respectively.

C1 is the oscillator frequency selection capacitor found in *Figure 1*.

FIGURE 8. Inverting Regulator

$V_{in} = 5V$
 $V_o = -15V$
 $V_{ripple} = 5\text{ mV}$
 $I_o = 300\text{ mA}$, $I_{min} = 60\text{ mA}$
 $f_{osc} = 50\text{ kHz}$
 $R1 = 160\text{ k}\Omega$, $R2 = 10\text{ k}\Omega$
 $R3 = 0.01\text{ }\Omega$, $R4 = 190\text{ }\Omega$
 $R5 = 82\text{ }\Omega$, $R6 = 220\text{ k}\Omega$
 $C1 = 1820\text{ pF}$
 $C2 = 1000\text{ }\mu\text{F}$
 $C3 = 20\text{ pF}$
 $C4 = 0.0022\text{ }\mu\text{F}$
 $L1 = 150\text{ }\mu\text{H}$
 $D1 = 1N5818$

TL/H/8711-12

$$C2 \geq I_o (V_o - V_{in}) / (f_{osc} V_o V_{ripple}).$$

D1 is a Schottky type diode such as a 1N5818 or 1N5819.

L1 is found as described in the buck converter section.

INVERTING REGULATOR

Figure 7 shows the basic configuration for an inverting regulator. The input voltage is of a positive polarity, but the output is negative. The output may be less than, equal to, or greater in magnitude than the input. The relationship between the magnitude of the input voltage and the output voltage is $V_o = V_{in} \times (t_{on}/t_{off})$.

TL/H/8711-10

FIGURE 7.

Figure 8 shows an LM1578 configured as a 5V to -15V polarity inverter with an output current of 300 mA, a load regulation of 44 mV (60 mA to 300 mA) and a line regulation of 50 mV ($4.5V \leq V_{in} \leq 8.5V$).

$$R1 = (|V_o| + 1) R2 \text{ where } R2 = 10\text{ k}\Omega.$$

$$R3 = V/(I_{IND}(\text{max}, \text{DC}) + 0.5 \Delta I_o).$$

$$R4 = 10V_{BE1}B_f/(I_{IND}(\text{max}, \text{DC}) + 0.5 \Delta I_o)$$

where:

V , V_{BE1} , V_{sat} , and B_f are defined in the "Buck Converter with Boosted Output Current" section.

ΔI_o is defined in the "Buck Regulator" section.

R5 is defined in the "Buck with Boosted Output Current" section.

R6 serves the same purpose as R4 in the Boost Regulator circuit and is typically 220 k Ω .

C1, C3 and C4 are defined in the "Boost Regulator" section.

$$C2 \geq I_o |V_o| / [f_{osc} (|V_o| + V_{in}) V_{ripple}]$$

L1 is found as outlined in the section on buck converters, using the inductance chart for the invert configuration and 20% discontinuity.

Typical Applications (Continued)

BUCK-BOOST REGULATOR

The Buck-Boost Regulator, shown in *Figure 9*, may step a voltage up or down, depending upon whether or not the desired output voltage is greater or less than the input voltage. In this case, the output voltage is 12V with an input voltage from 9V to 15V. The circuit exhibits an efficiency of 75%, with a load regulation of 60 mV (10 mA to 100 mA) and a line regulation of 52 mV.

$$R1 = (V_o - 1)/R2 \text{ where } R2 = 10 \text{ k}\Omega$$

$$R3 = V_o/0.75A$$

R4, C1, C3 and C4 are defined in the "Boost Regulator" section.

D1 and D2 are Schottky type diodes such as the 1N5818 or 1N5819.

$$C2 \geq \frac{(I_o/V_{\text{ripple}})(V_o + 2V_d)}{[f_{\text{osc}}(V_{\text{in}} + V_o + 2V_d - V_{\text{sat}} - V_{\text{sat1}})]}$$

where:

V_d is the forward voltage drop of the diodes.

V_{sat} is the saturation voltage of the LM1578 output transistor.

V_{sat1} is the saturation voltage of transistor Q1.

$$L1 \geq (V_{\text{in}} - V_{\text{sat}} - V_{\text{sat1}})(t_{\text{on}}/I_p)$$

where:

$$t_{\text{on}} = \frac{(1/f_{\text{osc}})(V_o + 2V_d)}{(V_o + V_{\text{in}} + 2V_d - V_{\text{sat}} - V_{\text{sat1}})}$$

$$I_p = \frac{2I_o(V_{\text{in}} + V_o + 2V_d - V_{\text{sat}} - V_{\text{sat1}})}{(V_{\text{in}} - V_{\text{sat}} - V_{\text{sat1}})}$$

TL/H/8711-14

FIGURE 10. RS-232 Line Driver Power Supply

Typical Applications (Continued)

Capacitor C1 sets the oscillator frequency and is selected from Figure 1.

Capacitor C2 serves as a compensation capacitor for synchronous operation and a value of 10 to 50 pF should be sufficient for most applications.

A minimum value for an ideal output capacitor C3, could be calculated as $C = I \times t / \Delta V$ where I is the load current, t is the transistor on time (typically $0.4/f_{OSC}$), and ΔV is the peak-to-peak output voltage ripple. A larger output capacitor than this theoretical value should be used since electrolytics have poor high frequency performance. Experience has shown that a value from 5 to 10 times the calculated value should be used.

For good efficiency, the diodes must have a low forward voltage drop and be fast switching. 1N5819 Schottky diodes work well.

Transformer selection should be picked for an output transistor "on" time of $0.4/f_{OSC}$, and a primary inductance high enough to prevent the output transistor switch from ramping higher than the transistor's rating of 750 mA. Pulse Engineering (San Diego, Calif.) and Renco Electronics, Inc. (Deer Park, N.Y.) can provide further assistance in selecting the proper transformer for a specific application need. The transformer used in Figure 10 was a Pulse Engineering PE-64287.

CURRENT LIMIT

As mentioned in the functional description, the current limit terminal may be referenced to either the V_{IN} or the ground terminal. Resistor, R3 converts the current to be sensed into a voltage for current limit detection.

Current Limit Ground Referred

TL/H/8711-15

Current Limit V_{IN} Referred

TL/H/8711-16

CURRENT LIMIT TRANSIENT SUPPRESSION

When noise spikes and switching transients interfere with proper current limit operation, R1 and C1 act together as a low pass filter to control the current limit circuitry's response time.

Because the sense current of the current limit terminal varies according to where it is referenced, R1 should be less than 2 k Ω when referenced to ground, and less than 100 Ω when referenced to V_{IN} .

Current Limit Transient Suppressor Ground Referred

TL/H/8711-17

Current Limit Transient Suppressor V_{IN} Referred

TL/H/8711-18

C. L. SENSE VOLTAGE MULTIPLICATION

When a larger sense resistor value is desired, the voltage divider network, consisting of R1 and R2, may be used. This effectively multiplies the sense voltage by $(1 + R1/R2)$. Also, R1 can be replaced by a diode to increase current limit sense voltage to about 800 mV (diode $V_f + 110$ mV).

Current Limit Sense Voltage Multiplication Ground Referred

TL/H/8711-19

Typical Applications (Continued)

Current Limit Sense Voltage Multiplication V_{IN} Referred

TL/H/8711-20

UNDER-VOLTAGE LOCKOUT

Under-voltage lockout is accomplished with few external components. When V_{IN} becomes lower than the zener breakdown voltage, the output transistor is turned off. This occurs because diode D1 will then become forward biased, allowing resistor R3 to sink a greater current from the non-inverting input than is sunk by the parallel combination of R1 and R2 at the inverting terminal. R3 should be one-fifth of the value of R1 and R2 in parallel.

Under Voltage Lockout

TL/H/8711-22

MAXIMUM DUTY CYCLE LIMITING

The maximum duty cycle can be externally limited by adjusting the charge to discharge ratio of the oscillator capacitor with a single external resistor. Typical values are 50 μ A for the charge current, 450 μ A for the discharge current, and a voltage swing from 200 mV to 750 mV. Therefore, R1 is selected for the desired charging and discharging slopes and C1 is readjusted to set the oscillator frequency.

Maximum Duty Cycle Limiting

TL/H/8711-21

DUTY CYCLE ADJUSTMENT

When manual or mechanical selection of the output transistor's duty cycle is needed, the circuit shown below may be used. The output will turn on with the beginning of each oscillator cycle and turn off when the current sunk by R2 and R3 from the non-inverting terminal becomes greater than the current sunk from the inverting terminal.

R1 should be less than 500 k Ω but greater than 100 k Ω to prevent loading of the oscillator. R2 should be approximately 100 k Ω . R3 is used to adjust the duty cycle.

When the sum of R2 and R3 is twice the value of R1, the duty cycle will be about 50%. Capacitor C1 may be electrolytic to lower the oscillator frequency below 1 Hz.

Duty Cycle Adjustment

TL/H/8711-23

REMOTE SHUTDOWN

The LM1578 may be remotely shutdown by sinking a greater current from the non-inverting input than from the inverting input. This may be accomplished by selecting resistor R3 to be approximately one-half the value of R1 and R2 in parallel.

Typical Applications (Continued)

Remote Shutdown—Shutdown Occurs When V_L is High

TL/H/8711-24

SYNCHRONIZING DEVICES

When several devices are to be operated at once, their oscillators may be synchronized by the application of an external signal. This drive signal should be a pulse waveform with a minimum pulse width of 2 μ sec. and an amplitude from

1.5V to 2.0V. The signal source must be capable of 1.) driving capacitive loads and 2.) delivering up to 500 μ A for each LM1578.

Capacitors C1 thru CN are to be selected for a 20% slower frequency than the synchronization frequency.

LM2925 Low Dropout Regulator with Delayed Reset

General Description

The LM2925 features a low dropout, high current regulator. Also included on-chip is a reset function with an externally set delay time. Upon power up, or after the detection of any error in the regulated output, the reset pin remains in the active low state for the duration of the delay. Types of errors detected include any that cause the output to become unregulated: low input voltage, thermal shutdown, short circuit, input transients, etc. No external pull-up resistor is necessary. The current charging the delay capacitor is very low, allowing long delay times.

Designed primarily for automotive applications, the LM2925 and all regulated circuitry are protected from reverse battery installations or 2 battery jumps. During line transients, such as a load dump (60V) when the input voltage to the regulator can momentarily exceed the specified maximum operating voltage, the 0.75A regulator will automatically shut down to protect both internal circuits and the load. The LM2925 cannot be harmed by temporary mirror-image insertion. Familiar regulator features such as short circuit and thermal overload protection are also provided.

Features

- Output current in excess of 750 mA
- Externally set delay for reset
- Input-output differential less than 0.6V at 0.5A
- Reverse battery protection
- 60V load dump protection
- -50V reverse transient protection
- Short circuit protection
- Internal thermal overload protection
- Available in plastic TO-220
- Long delay times available
- 100% electrical burn-in in thermal limit

Typical Application Circuit

*Required if regulator is located far from power supply filter.

**C_{OUT} must be at least 10 μF to maintain stability. May be increased without bound to maintain regulation during transients. Locate as close as possible to the regulator. This capacitor must be rated over the same operating temperature range as the regulator. The equivalent series resistance (ESR) of this capacitor should be less than 1Ω over the expected operating temperature range.

Definition of Terms

Dropout Voltage: The input-output voltage differential at which the circuit ceases to regulate against further reduction in input voltage. Measured when the output voltage has dropped 100 mV from the nominal value obtained at 14V input, dropout voltage is dependent upon load current and junction temperature.

Input Voltage: The DC voltage applied to the input terminals with respect to ground.

Input-Output Differential: The voltage difference between the unregulated input voltage and the regulated output voltage for which the regulator will operate.

Line Regulation: The change in output voltage for a change in the input voltage. The measurement is made under conditions of low dissipation or by using pulse techniques such that the average chip temperature is not significantly affected.

Load Regulation: The change in output voltage for a change in load current at constant chip temperature.

Long Term Stability: Output voltage stability under accelerated life-test conditions after 1000 hours with maximum rated voltage and junction temperature.

Output Noise Voltage: The rms AC voltage at the output, with constant load and no input ripple, measured over a specified frequency range.

Quiescent Current: The part of the positive input current that does not contribute to the positive load current. The regulator ground lead current.

Ripple Rejection: The ratio of the peak-to-peak input ripple voltage to the peak-to-peak output ripple voltage.

Temperature Stability of V_O : The percentage change in output voltage for a thermal variation from room temperature to either temperature extreme.

Application Hints

EXTERNAL CAPACITORS

The LM2925 output capacitor is required for stability. Without it, the regulator output will oscillate, sometimes by many volts. Though the 10 μ F shown is the minimum recommended value, actual size and type may vary depending upon the application load and temperature range. Capacitor effective series resistance (ESR) also effects the IC stability. Since ESR varies from one brand to the next, some bench work may be required to determine the minimum capacitor value to use in production. Worst-case is usually determined at the minimum junction and ambient temperature and maximum load expected.

Output capacitors can be increased in size to any desired value above the minimum. One possible purpose of this would be to maintain the output voltages during brief conditions of negative input transients that might be characteristic of a particular system.

Capacitors must also be rated at all ambient temperatures expected in the system. Many aluminum type electrolytics will freeze at temperatures less than -30°C , reducing their effective capacitance to zero. To maintain regulator stability down to -40°C , capacitors rated at that temperature (such as tantalums) must be used.

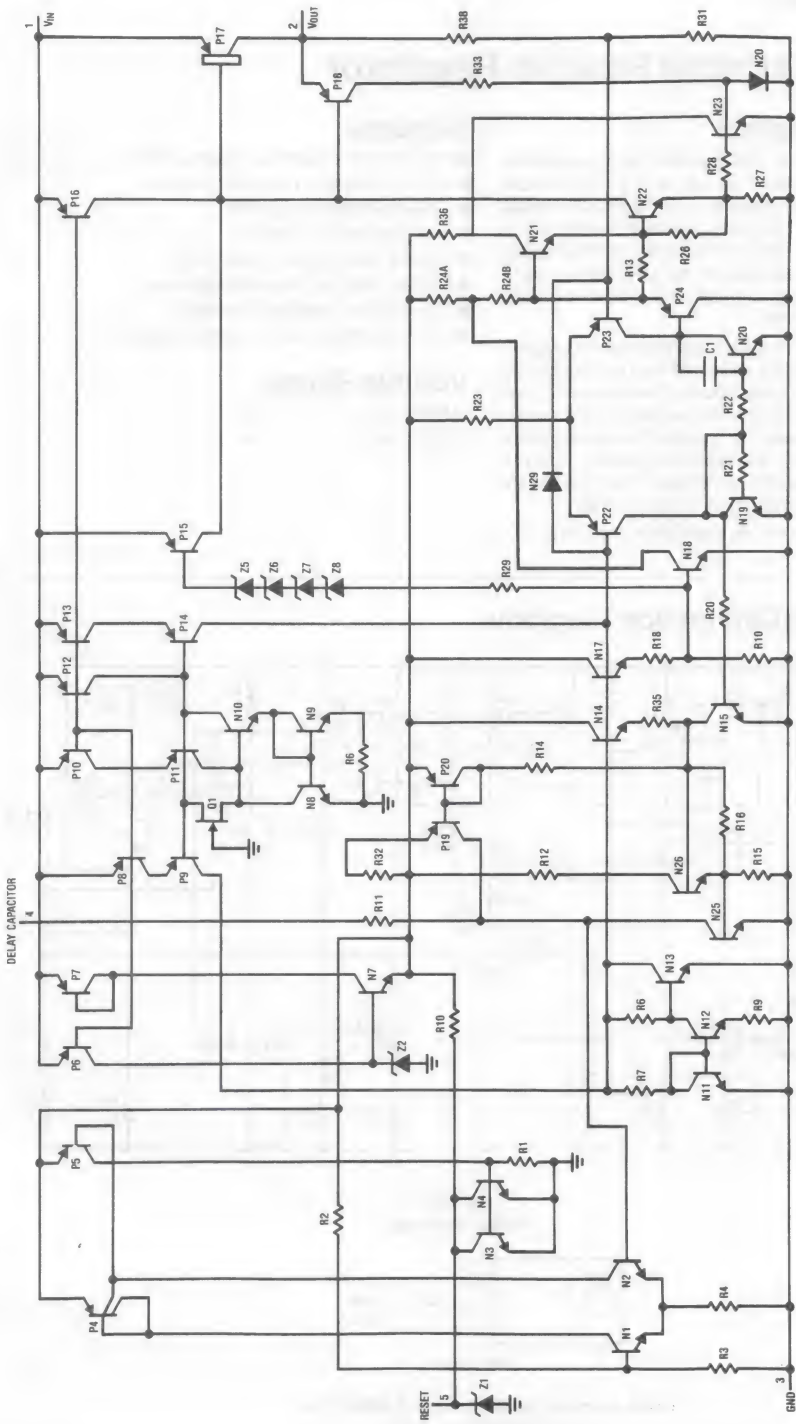

RESET OUTPUT

The range of values for the delay capacitor is limited only by stray capacitances on the lower extreme and capacitance leakage on the other. Thus, delay times from microseconds to seconds are possible. The low charging current, typically 2.0 microamps, allows the use of small, inexpensive disc capacitors for the nominal range of 100 to 500 milliseconds. This is the time required in many microprocessor systems for the clock oscillator to stabilize when initially powered up. The RESET output of the regulator will thus prevent erroneous data and/or timing functions to occur during this part of operation. The same delay is incorporated after any other fault condition in the regulator output is corrected.

FIGURE 3

LM2930 3-Terminal Positive Regulator

General Description

The LM2930 3-terminal positive regulator features an ability to source 150 mA of output current with an input-output differential of 0.6V or less. Efficient use of low input voltages obtained, for example, from an automotive battery during cold crank conditions, allows 5V circuitry to be properly powered with supply voltages as low as 5.6V. Familiar regulator features such as current limit and thermal overload protection are also provided.

Designed originally for automotive applications, the LM2930 and all regulated circuitry are protected from reverse battery installations or 2 battery jumps. During line transients, such as a load dump (40V) when the input voltage to the regulator can momentarily exceed the specified maximum operating voltage, the regulator will automatically shut down to protect both internal circuits and the load. The LM2930 cannot be harmed by temporary mirror-image insertion.

Fixed outputs of 5V and 8V are available in the plastic TO-220 power package.

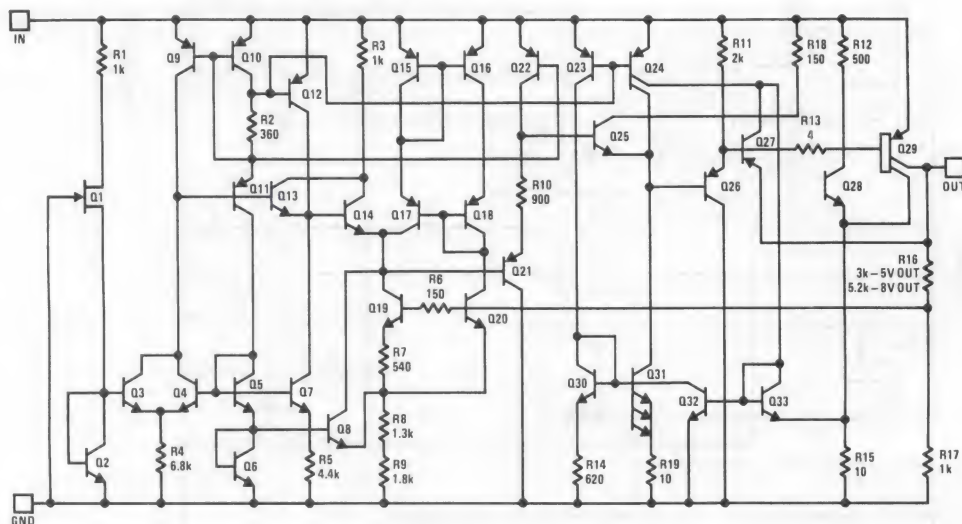

Features

- Input-output differential less than 0.6V
- Output current in excess of 150 mA
- Reverse battery protection
- 40V load dump protection
- Internal short circuit current limit
- Internal thermal overload protection
- Mirror-image insertion protection
- 100% electrical burn-in in thermal limit

LM2931 Series Low Dropout Regulators

General Description

The LM2931 positive voltage regulator features a very low quiescent current of 1 mA or less when supplying 10 mA loads. This unique characteristic and the extremely low input-output differential required for proper regulation (0.2V for output currents of 10 mA) make the LM2931 the ideal regulator for standby power systems. Applications include memory standby circuits, CMOS and other low power processor power supplies as well as systems demanding as much as 100 mA of output current.

Designed originally for automotive applications, the LM2931 and all regulated circuitry are protected from reverse battery installations or 2 battery jumps. During line transients, such as a load dump (60V) when the input voltage to the regulator can momentarily exceed the specified maximum operating voltage, the regulator will automatically shut down to protect both internal circuits and the load. The LM2931 cannot be harmed by temporary mirror-image insertion. Familiar regulator features such as short circuit and thermal overload protection are also provided.

Fixed output of 5V is available in the plastic TO-220 power package or the popular TO-92 package. An adjustable output version, with on/off switch, is available in a 5-lead TO-220 package.

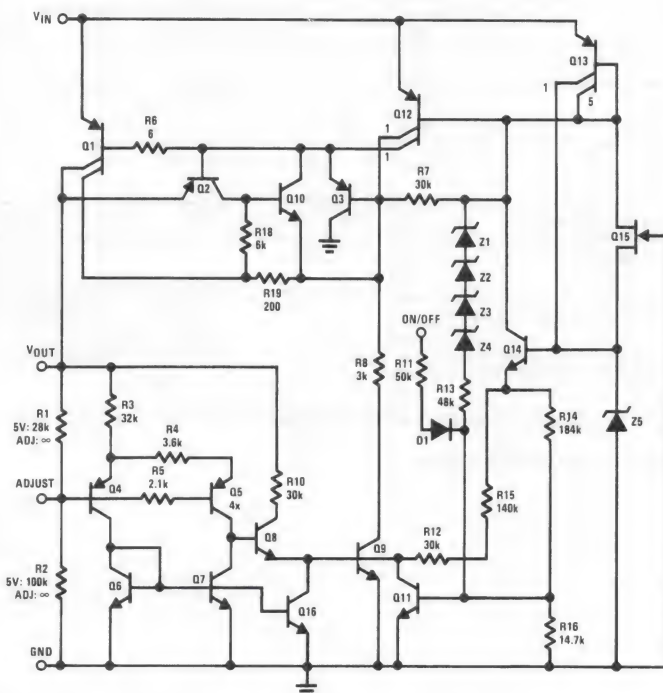

Features

- Very low quiescent current
- Output current in excess of 100 mA
- Input-output differential less than 0.6V
- Reverse battery protection
- 60V load dump protection
- -50V reverse transient protection
- Short circuit protection
- Internal thermal overload protection
- Mirror-image insertion protection
- Available in plastic TO-220 or TO-92
- Available as adjustable with TTL compatible switch
- 100% electrical burn-in in thermal limit

Output Voltage Options

Typical Applications

LM2931 Adjustable

TL/H/5254-4

$$V_{OUT} = \text{Reference Voltage} \times \frac{R1 + R2}{R1}$$

Note: Using 28k for R1 will automatically compensate for errors in V_{OUT} due to the input bias current of the ADJ pin (approximately 1 μA).

*Required if regulator is located far from power supply filter.

** C_{OUT} must be at least 22 μF to maintain stability. May be increased without bound to maintain regulation during transients. Locate as close as possible to the regulator. This capacitor must be rated over the same operating temperature range as the regulator. The equivalent series resistance (ESR) of this capacitor should be less than 1 Ω over the expected operating temperature range.

Application Hints

One of the distinguishing factors of the LM2931 series regulators is the requirement of an output capacitor for device stability. The value required varies greatly depending upon the application circuit and other factors. Thus some comments on the characteristics of both capacitors and the regulator are in order.

High frequency characteristics of electrolytic capacitors depend greatly on the type and even the manufacturer. As a result, a value of capacitance that works well with the LM2931 for one brand or type may not necessarily be sufficient with an electrolytic of different origin. Sometimes actual bench testing, as described later, will be the only means to determine the proper capacitor and value. Experience has shown that, as a rule of thumb, the more expensive and higher quality electrolytics generally allow a smaller value for regulator stability. As an example, while a high-quality 100 μF aluminum electrolytic covers all general application circuits, similar stability can be obtained with a tantalum electrolytic of only 47 μF . This factor of two can generally be applied to any special application circuit also.

Another critical characteristic of electrolytics is their performance over temperature. While the LM2931 is designed to operate to -40°C , the same is not always true with all electrolytics (hot is generally not a problem). The electrolyte in many aluminum types will freeze around -30°C , reducing their effective value to zero. Since the capacitance is needed for regulator stability, the natural result is oscillation (and lots of it) at the regulator output. For all application circuits where cold operation is necessary, the output capacitor must be rated to operate at the minimum temperature. By coincidence, worst-case stability for the LM2931 also occurs at minimum temperatures. As a result, in applications where the regulator junction temperature will never be less than 25°C , the output capacitor can be reduced approximately by a factor of two over the value needed for the entire temperature range. To continue our example with the tantalum electrolytic, a value of only 22 μF would probably thus suffice. For high-quality aluminum, 47 μF would be adequate in such an application.

Another regulator characteristic that is noteworthy is that stability decreases with higher output currents. This sensible fact has important connotations. In many applications, the LM2931 is operated at only a few milliamps of output current or less. In such a circuit, the output capacitor can be further reduced in value. As a rough estimation, a circuit that is required to deliver a maximum of 10 mA of output current from the regulator would need an output capacitor of only half the value compared to the same regulator required to deliver the full output current of 100 mA. If the example of the tantalum capacitor in the circuit rated at 25°C junction temperature and above were continued to include a maximum of 10 mA of output current, then the 22 μF output capacitor could be reduced to only 10 μF .

In the case of the LM2931CT adjustable regulator, the minimum value of output capacitance is a function of the output voltage. As a general rule, the value decreases with higher output voltages, since internal loop gain is reduced.

At this point, the procedure for bench testing the minimum value of an output capacitor in a special application circuit should be clear. Since worst-case occurs at minimum operating temperatures and maximum operating currents, the entire circuit, including the electrolytic, should be cooled to the minimum temperature. The input voltage to the regulator should be maintained at 0.6V above the output to keep internal power dissipation and die heating to a minimum. Worst-case occurs just after input power is applied and before the die has had a chance to heat up. Once the minimum value of capacitance has been found for the brand and type of electrolytic in question, the value should be doubled for actual use to account for production variations both in the capacitor and the regulator. (All the values in this section and the remainder of the data sheet were determined in this fashion.)

Definition of Terms

Dropout Voltage: The input-output voltage differential at which the circuit ceases to regulate against further reduction in input voltage. Measured when the output voltage has dropped 100 mV from the nominal value obtained at 14V input, dropout voltage is dependent upon load current and junction temperature.

Input Voltage: The DC voltage applied to the input terminals with respect to ground.

Input-Output Differential: The voltage difference between the unregulated input voltage and the regulated output voltage for which the regulator will operate.

Line Regulation: The change in output voltage for a change in the input voltage. The measurement is made under conditions of low dissipation or by using pulse techniques such that the average chip temperature is not significantly affected.

Load Regulation: The change in output voltage for a change in load current at constant chip temperature.

Long Term Stability: Output voltage stability under accelerated life-test conditions after 1000 hours with maximum rated voltage and junction temperature.

Output Noise Voltage: The rms AC voltage at the output, with constant load and no input ripple, measured over a specified frequency range.

Quiescent Current: That part of the positive input current that does not contribute to the positive load current. The regulator ground lead current.

Ripple Rejection: The ratio of the peak-to-peak input ripple voltage to the peak-to-peak output ripple voltage.

Temperature Stability of V_O : The percentage change in output voltage for a thermal variation from room temperature to either temperature extreme.

LM2935 Low Dropout Dual Regulator

General Description

The LM2935 positive voltage regulator features a low quiescent current of 3 mA or less when supplying 10 mA loads from the standby regulator output. This unique characteristic and the extremely low input-output differential required for proper regulation (0.55V for output currents of 10 mA) make the LM2935 the ideal regulator for power systems that include standby memory. Applications include processor power supplies demanding as much as 750 mA of output current.

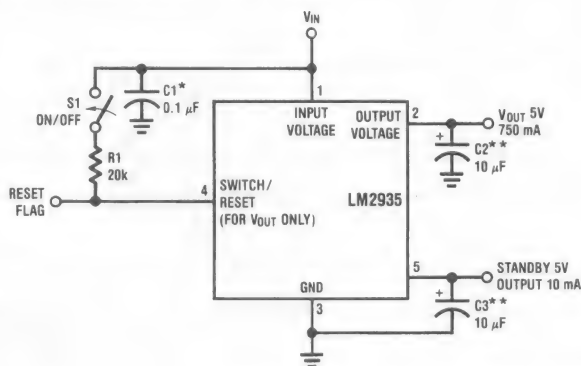

Designed originally for automotive applications, the LM2935 and all regulated circuitry are protected from reverse battery installations or 2 battery jumps. During line transients, such as a load dump (60V) when the input voltage to the regulator can momentarily exceed the specified maximum operating voltage, the 0.75A regulator will automatically shut down to protect both internal circuits and the load while the standby regulator will continue to power any standby load. The LM2935 cannot be harmed by temporary mirror-image insertion. Familiar regulator features such as short circuit and thermal overload protection are also provided.

Fixed outputs of 5V are available in the plastic TO-220 power package.

Features

- Two regulated outputs
- Output current in excess of 750 mA
- Low quiescent current standby regulator
- Input-output differential less than 0.6V at 0.5A
- Reverse battery protection
- 60V load dump protection
- -50V reverse transient protection
- Short circuit protection
- Internal thermal overload protection
- Available in plastic TO-220
- ON/OFF switch for high current output
- Reset error flag
- 100% electrical burn-in in thermal limit

Typical Application Circuit

*Required if regulator is located far from power supply filter.

**C_{OUT} must be at least 10 μF to maintain stability. May be increased without bound to maintain regulation during transients. Locate as close as possible to the regulator. This capacitor must be rated over the same operating temperature range as the regulator. The equivalent series resistance (ESR) of this capacitor should be less than 1Ω over the expected operating temperature range.

Temperature Stability of V_O : The percentage change in output voltage for a thermal variation from room temperature to either temperature extreme.

Application Hints

EXTERNAL CAPACITORS

The LM2935 output capacitors are required for stability. Without them, the regulator outputs will oscillate, sometimes by many volts. Though the 10 μ F shown are the minimum recommended values, actual size and type may vary depending upon the application load and temperature range. Capacitor effective series resistance (ESR) also factors in the IC stability. Since ESR varies from one brand to the next, some bench work may be required to determine the minimum capacitor value to use in production. Worst-case is usually determined at the minimum ambient temperature and maximum load expected.

Output capacitors can be increased in size to any desired value above the minimum. One possible purpose of this would be to maintain the output voltage during brief conditions of negative input transients that might be characteristic of a particular system.

Capacitors must also be rated at all ambient temperatures expected in the system. Many aluminum type electrolytics will freeze at temperatures less than -30°C , reducing their effective capacitance to zero. To maintain regulator stability down to -40°C , capacitors rated at that temperature (such as tantalums) must be used.

No capacitor must be attached to the ON/OFF and ERROR FLAG pin. Due to the internal circuits of the IC, oscillation on this pin could result.

STANDBY OUTPUT

The LM2935 differs from most fixed voltage regulators in that it is equipped with two regulator outputs instead of one. The additional output is intended for use in systems requiring standby memory circuits. While the high current regulator output can be controlled with the ON/OFF pin described below, the standby output remains on under all conditions as long as sufficient input voltage is applied to the IC. Thus, memory and other circuits powered by this output remain unaffected by positive line transients, thermal shutdown, etc.

The standby regulator circuit is designed so that the quiescent current to the IC is very low ($<3\text{ mA}$) when the other regulator output is off.

In applications where the standby output is not needed, it may be disabled by connecting a resistor from the standby output to the supply voltage. This eliminates the need for a more expensive capacitor on the output to prevent unwanted oscillations. The value of the resistor depends upon the minimum input voltage expected for a given system. Since the standby output is shunted with an internal 5.7V zener (Figure 3), the current through the external resistor should be sufficient to bias R2 and R3 up to this point. Approximately 60 μA will suffice, resulting in a 10k external resistor for most applications (Figure 4).

TL/H/5232-6

FIGURE 4. Disabling Standby Output to Eliminate C3

HIGH CURRENT OUTPUT

Unlike the standby regulated output, which must remain on whenever possible, the high current regulated output is fault protected against overvoltage and also incorporates thermal shutdown. If the input voltage rises above approximately 30V (e.g., load dump), this output will automatically shut down. This protects the internal circuitry and enables the IC to survive higher voltage transients than would otherwise be expected. Thermal shutdown is effective against die overheating since the high current output is the dominant source of power dissipation in the IC.

ON/OFF AND ERROR FLAG PIN

This pin has the ability to serve a dual purpose if desired. When controlled in the manner shown in Figure 1 (common in automotive systems where S1 is the ignition switch), the pin also serves as an output flag that is active low whenever a fault condition is detected with the high current regulated output. In other words, under normal operating conditions, the output voltage of this pin is high (5V). This is set by an internal clamp. If the high current

Application Hints (Continued)

output becomes unregulated for any reason (line transients, short circuit, thermal shutdown, low input voltage, etc.) the pin switches to the active low state, and is capable of sinking several milliamps. This output signal can be used to initiate any reset or start-up procedure that may be required of the system.

The ON/OFF pin can also be driven directly from logic circuits. The only requirement is that the 20k pull-up resistor

remain in place (Figure 5). This will not affect the logic gate since the voltage on this pin is limited by the internal clamp in the LM2935 to 5V. The error flag is sacrificed in this arrangement since the maximum sink capability of the pin in the active low state (approximately 5 mA) is usually not sufficient to pull down the active high logic gate. Of course, the flag can be retained if the driving gate is open collector logic.

LM2940 1A Low Dropout Regulator

General Description

The LM2940 positive voltage regulator features the ability to source 1A of output current with a dropout voltage of typically 0.5V and a maximum of 1V over the entire temperature range. Furthermore, a quiescent current reduction circuit has been included which reduces the ground current when the differential between the input voltage and the output voltage exceeds approximately 3V. The quiescent current with 1A of output current and an input-output differential of 5V is therefore only 30 mA. Higher quiescent currents only exist when the regulator is in the dropout mode ($V_{in} - V_{out} \leq 3V$).

Designed also for vehicular applications, the LM2940 and all regulated circuitry are protected from reverse battery installations or 2 battery jumps. During line transients, such as load dump (60V) when the input voltage can momentarily exceed the specified maximum operating voltage, the regulator will automatically shut down to protect both the internal circuits and the load. The LM2940 cannot be harmed by temporary mirror-image insertion. Familiar regulator features such as short circuit and thermal overload protection are also provided.

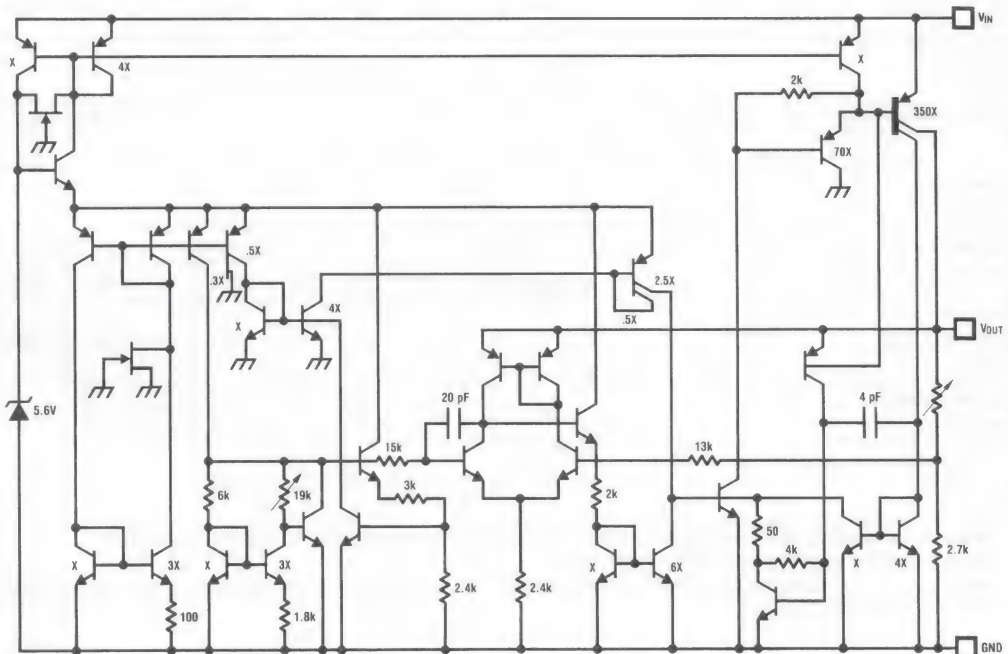

Features

- Dropout voltage typically 0.5V @ $I_o = 1A$
- Output current in excess of 1A
- Output trimmed before assembly
- Reverse battery protection
- Internal short circuit current limit
- Mirror image insertion protection
- 100% electrical burn-in in thermal limit

Output Voltages

LM2984C Microprocessor Power Supply System

General Description

The LM2984C positive voltage regulator features three independent and tracking outputs capable of delivering the power for logic circuits, peripheral sensors and standby memory in a typical microprocessor system. The LM2984C includes circuitry which monitors both its own high-current output and also an external μP . If any error conditions are sensed in either, a reset error flag is set and maintained until the malfunction terminates. Since these functions are included in the same package with the three regulators, a great saving in board space can be realized in the typical microprocessor system. The LM2984C also features very low dropout voltages on each of its three regulator outputs (0.6V at the rated output current). Furthermore, the quiescent current can be reduced to 1 mA in the standby mode.

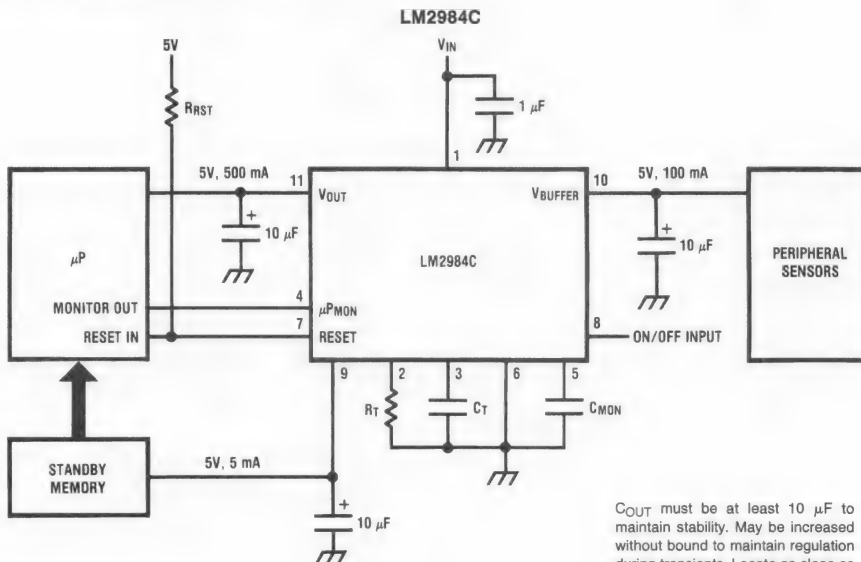

Designed also for vehicular applications, the LM2984C and all regulated circuitry are protected from reverse battery installations or 2-battery jumps. Familiar regulator features such as short circuit and thermal overload protection are

also provided. Fixed outputs of 5V are available in the plastic TO-220 power package.

Features

- Three low dropout tracking regulators
- Output current in excess of 500 mA
- Low quiescent current standby regulator
- Microprocessor malfunction RESET flag
- Delayed RESET on power-up
- Accurate pretrimmed 5V outputs
- Reverse battery protection
- Overvoltage protection
- Reverse transient protection
- Short circuit protection
- Internal thermal overload protection
- ON/OFF switch for high current outputs
- 100% electrical burn-in in thermal limit

Note 1: Thermal resistance without a heatsink for junction-to-case temperature is $3^\circ C/W$. Thermal resistance case-to-ambient is $40^\circ C/W$.

Note 2: Tested Limits are guaranteed and 100% production tested.

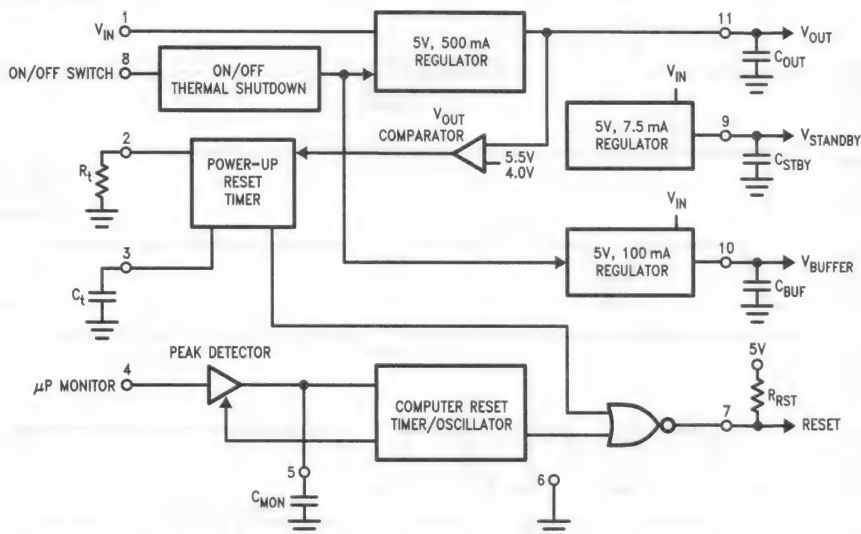

Note 3: Design Limits are guaranteed (but not 100% production tested) over the indicated temperature and supply voltage range. These limits are not used to calculate outgoing quality levels.

Note 4: An internal comparator detects when the main regulator output (V_{OUT}) drops below 4.0V or rises above 5.5V. If either condition exists at the output, the Reset Error Flag is held low until the error condition has terminated. The Reset Error Flag is then allowed to go high again after a delay set by R_t and C_t . (See Applications Section.)

Note 5: This parameter is a measure of how short a pulse can be detected at the μP Monitor Input. This parameter is primarily influenced by the value of C_{mon} . (See Typical Performance Characteristics and Applications Section.)

Note 6: To ensure constant junction temperature, low duty cycle pulse testing is used.

Block Diagram

TL/H/8821-2

Pin Description

Pin No.	Pin Name	Comments
1	V _{IN}	Positive supply input voltage
2	R _t	Sets internal timing currents
3	C _t	Sets power-up reset timing
4	μP _{mon}	Microcomputer monitor input
5	C _{mon}	Sets μC monitor timing
6	Ground	Regulator ground
7	Reset	Reset error flag output
8	ON/OFF	Enables/disables high current regulators
9	V _{standby}	Standby regulator output (7.5 mA)
10	V _{buffer}	Buffer regulator output (100 mA)
11	V _{OUT}	Main regulator output (500 mA)

External Components

Component	Typical Value	Component Range	Comments
C _{IN}	1 μF	0.47 μF–10 μF	Required if device is located far from power supply filter.
R _t	130k	24k–1.2M	Sets internal timing currents.
C _t	0.33 μF	0.033 μF–3.3 μF	Sets power-up reset delay.
C _{tc}	0.01 μF	0.001 μF–0.1 μF	Establishes time constant of AC coupled computer monitor.
R _{tc}	10k	1k–100k	Establishes time constant of AC coupled computer monitor. (See applications section.)
C _{mon}	0.47 μF	0.047 μF–4.7 μF	Sets time window for computer monitor. Also determines period and pulse width of computer malfunction reset. (See applications section.)
R _{rst}	10k	5k–100k	Load for open collector reset output. Determined by computer reset input requirements.
C _{stby}	10 μF	10 μF–no bound	A 10 μF is required for stability but larger values can be used to maintain regulation during transient conditions.
C _{buf}	10 μF	10 μF–no bound	A 10 μF is required for stability but larger values can be used to maintain regulation during transient conditions.
C _{OUT}	10 μF	10 μF–no bound	A 10 μF is required for stability but larger values can be used to maintain regulation during transient conditions.

Application Hints

OUTPUT CAPACITORS

The LM2984C output capacitors are required for stability. Without them, the regulator outputs will oscillate, sometimes by many volts. Though the 10 μ F shown are the minimum recommended values, actual size and type may vary depending upon the application load and temperature range. Capacitor effective series resistance (ESR) also affects the IC stability. Since ESR varies from one brand to the next, some bench work may be required to determine the minimum capacitor value to use in production. Worst case is usually determined at the minimum ambient temperature and the maximum load expected.

Output capacitors can be increased in size to any desired value above the minimum. One possible purpose of this would be to maintain the output voltages during brief conditions of negative input transients that might be characteristic of a particular system.

Capacitors must also be rated at all ambient temperatures expected in the system. Many aluminum type electrolytics will freeze at temperatures less than -30°C , reducing their effective capacitance to zero. To maintain regulator stability down to -40°C , capacitors rated at that temperature (such as tantalums) must be used.

Each output **must** be terminated by a capacitor, even if it is not used.

STANDBY OUTPUT

The standby output is intended for use in systems requiring standby memory circuits. While the high current regulator outputs are controlled with the ON/OFF pin described later, the standby output remains on under all conditions as long as sufficient input voltage is supplied to the IC. Thus, memory and other circuits powered by this output remain unaffected by positive line transients, thermal shutdown, etc.

The standby regulator circuit is designed so that the quiescent current to the IC is very low (< 1.5 mA) when the other regulator outputs are off.

The capacitor on the output of this regulator can be increased without bound. This will help maintain the output voltage during negative input transients and will also help to reduce the noise on all three outputs. Because the other two track the standby output: therefore any noise reduction here will also reduce the other two noise voltages.

BUFFER OUTPUT

The buffer output is designed to drive peripheral sensor circuitry in a μ P system. It will track the standby and main regulator within a few millivolts in normal operation. Therefore, a peripheral sensor can be powered off this supply and have the same operating voltage as the μ P system. This is important if a ratiometric sensor system is being used.

The buffer output can be short circuited while the other two outputs are in normal operation. This protects the μ P system from disruption of power when a sensor wire, etc. is temporarily shorted to ground, i.e. only the sensor signal would be interrupted, while the μ P and memory circuits would remain operational.

The buffer output is similar to the main output in that it is controlled by the ON/OFF switch in order to save power in the standby mode. It is also fault protected against overvoltage and thermal overload. If the input voltage rises above approximately 30V (e.g. load dump), this output will automatically shut down. This protects the internal circuitry and enables the IC to survive higher voltage transients than would otherwise be expected. Thermal shutdown is necessary since this output is one of the dominant sources of power dissipation in the IC.

MAIN OUTPUT

The main output is designed to power relatively large loads, i.e. approximately 500 mA. It is therefore also protected against overvoltage and thermal overload.

This output will track the other two within a few millivolts in normal operation. It can therefore be used as a reference voltage for any signal derived from circuitry powered off the standby or buffer outputs. This is important in a ratiometric sensor system or any system requiring accurate matching of power supply voltages.

ON/OFF SWITCH

The ON/OFF switch controls the main output and the buffer output. The threshold voltage is compatible with most logic families and has about 20 mV of hysteresis to insure 'clean' switching from the standby mode to the active mode and vice versa. This pin can be tied to the input voltage through a 10 k Ω resistor if the regulator is to be powered continuously.

Application Hints (Continued)

POWER DOWN OVERRIDE

Another possible approach is to use a diode in series with the ON/OFF signal and another in series with the main output in order to maintain power for some period of time after the ON/OFF signal has been removed (see Figure 1). When the ON/OFF switch is initially pulled high through diode D1, the main output will turn on and supply power through diode D2 to the ON/OFF switch effectively latching the main output. An open collector transistor Q1 is connected to the ON/OFF pin along with the two diodes and forces the regulators off after a period of time determined by the μP . In this way, the μP can override a power down command and store data, do housekeeping, etc. before reverting back to the standby mode.

TL/H/8821-10

FIGURE 1. Power Down Override

RESET OUTPUT

This output is an open collector NPN transistor which is forced low whenever an error condition is present at the main output or when a μP error is sensed (see μP Monitor section). If the main output voltage drops below 4V or rises above 5.5V, the RESET output is forced low and held low for a period of time set by two external components, R_t and C_t . There is a slight amount of hysteresis in these two threshold voltages so that the RESET output has a fast rise and fall time compatible with the requirements of most μP RESET inputs.

DELAYED RESET

Resistor R_t and capacitor C_t set the period of time that the RESET output is held low after a main output error condition has been sensed. The delay is given by the formula:

$$T_{dly} = 1.2 R_t C_t \text{ (seconds)}$$

The delayed RESET will be initiated any time the main output is outside the 4V to 5.5V window, i.e. during power-up, short circuit, overvoltage, low line, thermal shutdown or power-down. The μP is therefore RESET whenever the output voltage is out of regulation. (It is important to note that a RESET is only initiated when the main output is in error. The buffer and standby outputs are not directly monitored for error conditions.)

μP MONITOR RESET

There are two distinct and independent error monitoring systems in the LM2984C. The one described above monitors the main regulator output and initiates a delayed RESET whenever this output is in error. The other error monitoring system is the μP watchdog. These two systems are OR'd together internally and both force the RESET output low when either type of error occurs.

This watchdog circuitry continuously monitors a pin on the μP that generates a positive going pulse during normal operation. The period of this pulse is typically on the order of milliseconds and the pulse width is typically on the order of 10's of microseconds. If this pulse ever disappears, the watchdog circuitry will time out and a RESET low will be sent to the μP . The time out period is determined by two external components, R_t and C_{mon} , according to the formula:

$$T_{window} = 0.82 R_t C_{mon} \text{ (seconds)}$$

The width of the RESET pulse is set by C_{mon} and an internal resistor according to the following:

$$RESET_{pw} = 2000 C_{mon} \text{ (seconds)}$$

A square wave signal can also be monitored for errors by filtering the C_{mon} input such that only the positive edges of the signal are detected. Figure 2 is a schematic diagram of a typical circuit used to differentiate the input signal. Resistor R_{tc} and capacitor C_{tc} pass only the rising edge of the square wave and create a short positive pulse suitable for the μP monitor input. If the incoming signal continues in a high state or in a low state for too long a period of time, a RESET low will be generated.

TL/H/8821-11

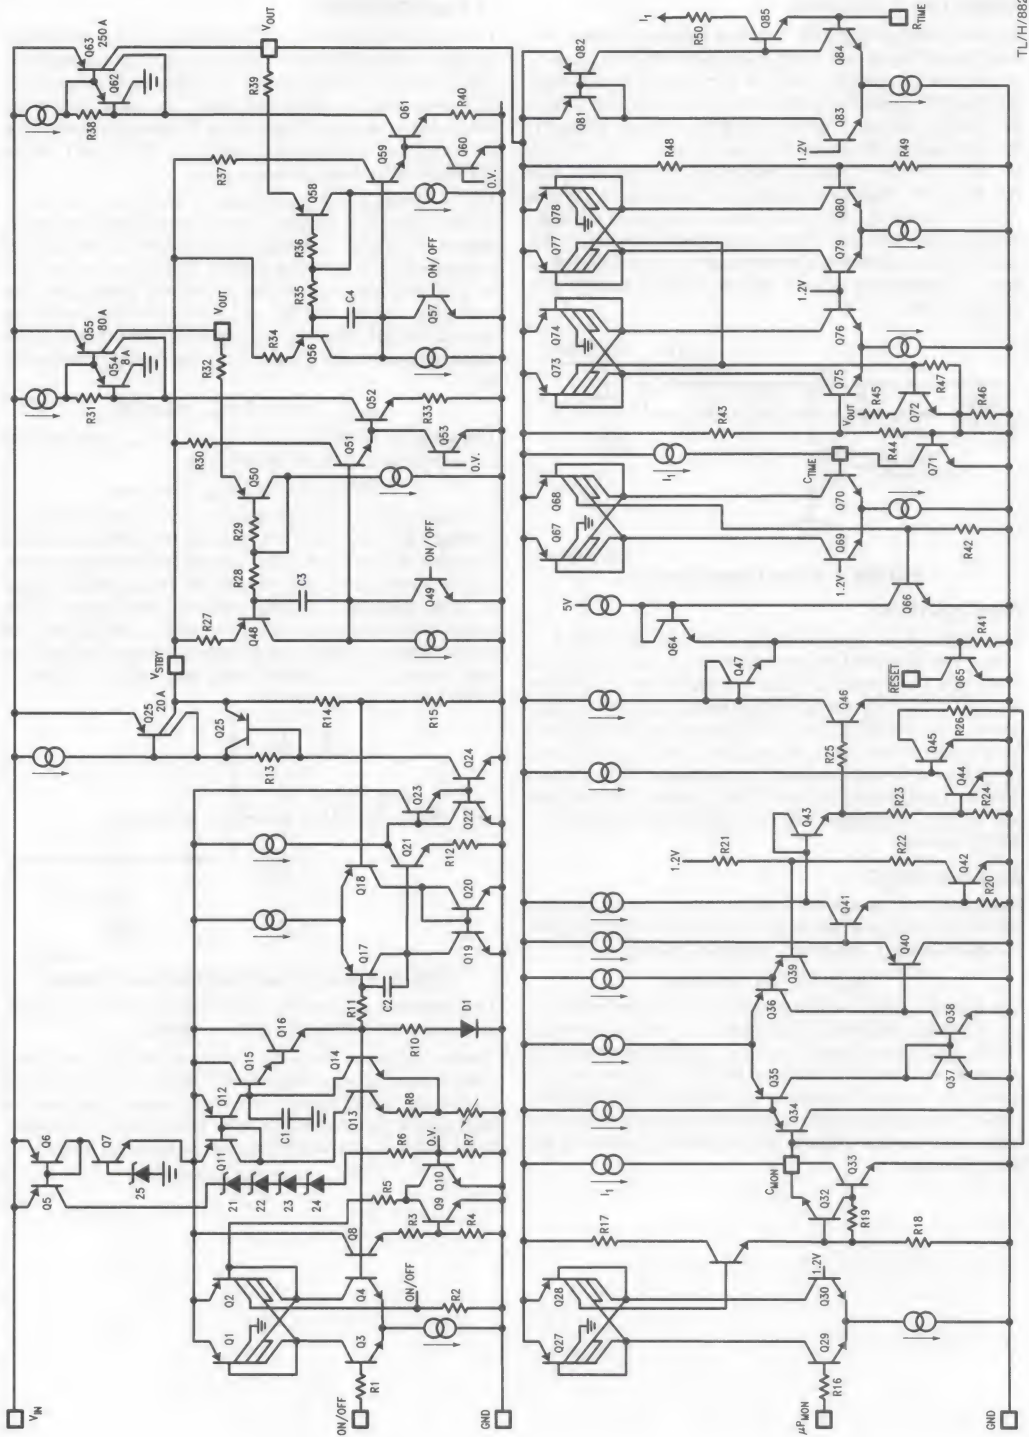

FIGURE 2. Monitoring Square Wave μP Signals

The threshold voltage and input characteristics of this pin are compatible with nearly all logic families.

There is a limit on the width of a pulse that can be reliably detected by the watchdog circuit. This is due to the output resistance of the transistor which discharges C_{mon} when a high state is detected at the input. The minimum detectable pulse width can be determined by the following formula:

$$PW_{min} = 20 C_{mon} \text{ (seconds)}$$

Equivalent Schematic Diagram

LM78XX Series Voltage Regulators

General Description

The LM78XX series of three terminal regulators is available with several fixed output voltages making them useful in a wide range of applications. One of these is local on card regulation, eliminating the distribution problems associated with single point regulation. The voltages available allow these regulators to be used in logic systems, instrumentation, HiFi, and other solid state electronic equipment. Although designed primarily as fixed voltage regulators these devices can be used with external components to obtain adjustable voltages and currents.

The LM78XX series is available in an aluminum TO-3 package which will allow over 1.0A load current if adequate heat sinking is provided. Current limiting is included to limit the peak output current to a safe value. Safe area protection for the output transistor is provided to limit internal power dissipation. If internal power dissipation becomes too high for the heat sinking provided, the thermal shutdown circuit takes over preventing the IC from overheating.

Considerable effort was expended to make the LM78XX series of regulators easy to use and minimize the number

of external components. It is not necessary to bypass the output, although this does improve transient response. Input bypassing is needed only if the regulator is located far from the filter capacitor of the power supply.

For output voltage other than 5V, 12V and 15V the LM117 series provides an output voltage range from 1.2V to 57V.

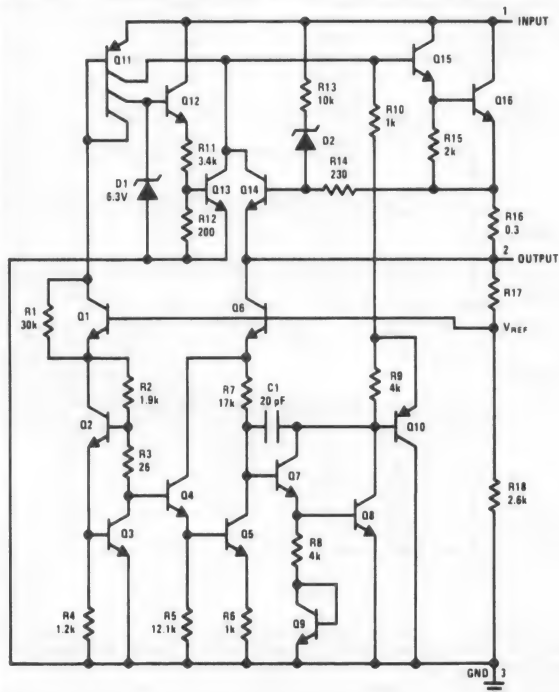

Features

- Output current in excess of 1A
- Internal thermal overload protection
- No external components required
- Output transistor safe area protection
- Internal short circuit current limit
- Available in the aluminum TO-3 package

Note 1: Thermal resistance of the TO-3 package (K, KC) is typically $4^\circ\text{C}/\text{W}$ junction to case and $35^\circ\text{C}/\text{W}$ case to ambient. Thermal resistance of the TO-220 package (T) is typically $4^\circ\text{C}/\text{W}$ junction to case and $50^\circ\text{C}/\text{W}$ case to ambient.

Note 2: All characteristics are measured with capacitor across the input of $0.22\text{ }\mu\text{F}$, and a capacitor across the output of $0.1\text{ }\mu\text{F}$. All characteristics except noise voltage and ripple rejection ratio are measured using pulse techniques ($t_w \leq 10\text{ ms}$, duty cycle $\leq 5\%$). Output voltage changes due to changes in internal temperature must be taken into account separately.

LM78LXX Series 3-Terminal Positive Regulators

General Description

The LM78LXX series of three terminal positive regulators is available with several fixed output voltages making them useful in a wide range of applications. When used as a zener diode/resistor combination replacement, the LM78LXX usually results in an effective output impedance improvement of two orders of magnitude, and lower quiescent current. These regulators can provide local on card regulation, eliminating the distribution problems associated with single point regulation. The voltages available allow the LM78LXX to be used in logic systems, instrumentation, HiFi, and other solid state electronic equipment. Although designed primarily as fixed voltage regulators these devices can be used with external components to obtain adjustment voltages and currents.

The LM78LXX is available in the metal three lead TO-39(H) the plastic TO-92 (Z), and SO-8 plastic. With adequate heat sinking the regulator can deliver 100 mA output current. Current limiting is included to limit the peak output current to a safe value. Safe area protection for the output transistors is provided to limit internal power dissipation. If internal power dissipation becomes too high for the heat sinking provided, the thermal shutdown circuit takes over preventing the IC from overheating.

For output voltage other than 5V, 12V and 15V the LM117L series provides an output voltage range from 1.2V to 37V.

Features

- Output voltage tolerances of $\pm 5\%$ (LM78LXXAC) over the temperature range
- Output current of 100 mA
- Internal thermal overload protection
- Output transistor safe area protection
- Internal short circuit current limit
- Available in plastic TO-92 and metal TO-39 and plastic SO-8 low profile packages

LM79XX Series 3-Terminal Negative Regulators

General Description

The LM79XX series of 3-terminal regulators is available with fixed output voltages of $-5V$, $-12V$, and $-15V$. These devices need only one external component—a compensation capacitor at the output. The LM79XX series is packaged in the TO-220 power package and is capable of supplying 1.5A of output current.

These regulators employ internal current limiting, safe area protection and thermal shutdown for protection against virtually all overload conditions.

Low ground pin current of the LM79XX series allows output voltage to be easily boosted above the preset value with a resistor divider. The low quiescent current drain of

these devices with a specified maximum change with line and load ensures good regulation in the voltage boosted mode.

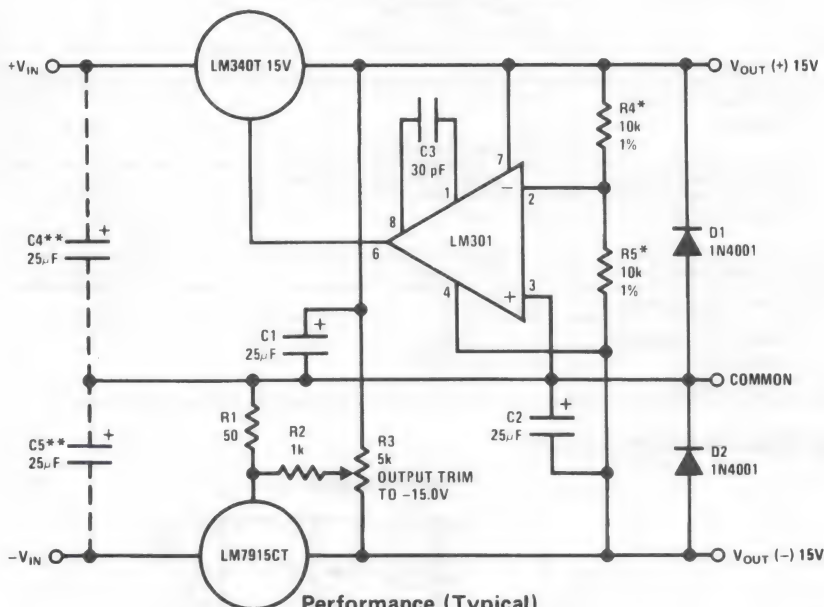

For applications requiring other voltages, see LM137 data sheet.

Features

- Thermal, short circuit and safe area protection
- High ripple rejection
- 1.5A output current
- 4% preset output voltage

Typical Applications

± 15V, 1 Amp Tracking Regulators

Performance (Typical)

	(-15)	(+15)
Load Regulation at $\Delta I_L = 1A$	40 mV	2 mV
Output Ripple, $C_{IN} = 3000 \mu F$, $I_L = 1A$	100 μV_{rms}	100 μV_{rms}
Temperature Stability	50 mV	50 mV
Output Noise 10 Hz $\leq f \leq 10$ kHz	150 μV_{rms}	150 μV_{rms}

*Resistor tolerance of R4 and R5 determine matching of (+) and (-) outputs.

**Necessary only if raw supply filter capacitors are more than 3" from regulators.

Note 1: For calculations of junction temperature rise due to power dissipation, thermal resistance junction to ambient (θ_{JA}) is $50^\circ\text{C}/\text{W}$ (no heat sink) and $5^\circ\text{C}/\text{W}$ (infinite heat sink).

Note 2: Regulation is measured at a constant junction temperature by pulse testing with a low duty cycle. Changes in output voltage due to heating effects must be taken into account.

Typical Applications (Continued)

Fixed Regulator

TL/H/7340-3

*Required if regulator is separated from filter capacitor by more than 3". For value given, capacitor must be solid tantalum. $25 \mu\text{F}$ aluminum electrolytic may be substituted.

†Required for stability. For value given, capacitor must be solid tantalum. $25 \mu\text{F}$ aluminum electrolytic may be substituted. Values given may be increased without limit.

For output capacitance in excess of $100 \mu\text{F}$, a high current diode from input to output (1N4001, etc.) will protect the regulator from momentary input shorts.

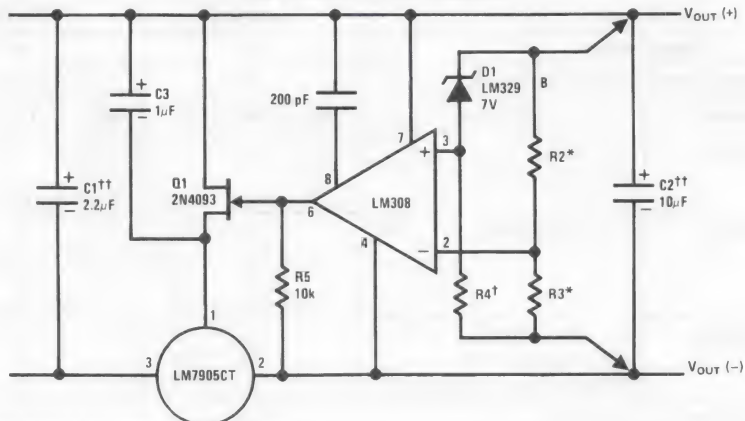

Dual Trimmed Supply

TL/H/7340-4

Typical Applications (Continued)

High Stability 1 Amp Regulator

Load and line regulation $< 0.01\%$ temperature stability $\leq 0.2\%$

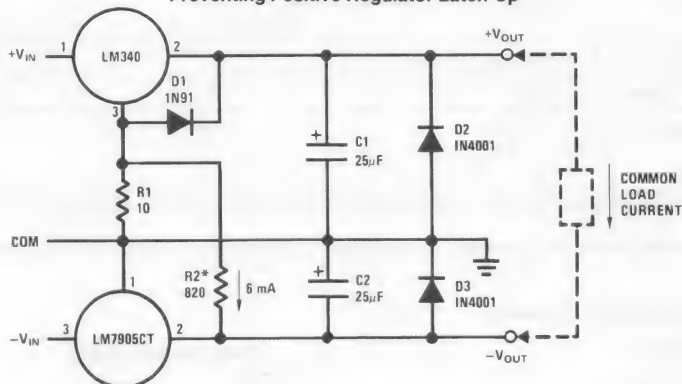

TL/H/7340-5

†Determine Zener current

††Solid tantalum

*Select resistors to set output voltage. 2 ppm/°C tracking suggested

Preventing Positive Regulator Latch-Up

TL/H/7340-6

R1 and D1 allow the positive regulator to "start-up" when $+V_{IN}$ is delayed relative to $-V_{IN}$ and a heavy load is drawn between the outputs. Without R1 and D1, most three-terminal regulators will not start with heavy (0.1 A-1 A) load current flowing to the negative regulator, even though the positive output is clamped by D2.

*R2 is optional. Ground pin current from the positive regulator flowing through R1 will increase $+V_{OUT} \approx 60$ mV if R2 is omitted.

Current Source

$$I_{OUT} = 1 \text{ mA} + \frac{5V}{R1}$$

TL/H/7340-7

LM79LXXAC Series 3-Terminal Negative Regulators

General Description

The LM79LXXAC series of 3-terminal negative voltage regulators features fixed output voltages of $-5V$, $-12V$, and $-15V$ with output current capabilities in excess of 100 mA. These devices were designed using the latest computer techniques for optimizing the packaged IC thermal/electrical performance. The LM79LXXAC series, even when combined with a minimum output compensation capacitor of 0.1 μF , exhibits an excellent transient response, a maximum line regulation of 0.07% V_O/V , and a maximum load regulation of 0.01% V_O/mA .

The LM79LXXAC series also includes, as self-protection circuitry: safe operating area circuitry for output transistor power dissipation limiting, a temperature independent short circuit current limit for peak output current limiting, and a thermal shutdown circuit to prevent excessive junction temperature. Although designed primarily as fixed voltage regulators, these devices may be combined with simple external circuitry for boosted and/or adjustable voltages and currents. The LM79LXXAC series is available in the 3-lead TO-92 package, and SO-8; 8 lead package.

For output voltage other than $-5V$, $-12V$ and $-15V$ the LM137L series provides an output voltage range from 1.2V to 47V.

Features

- Preset output voltage error is less than $\pm 5\%$ overload, line and temperature
- Specified at an output current of 100 mA
- Easily compensated with a small 0.1 μF output capacitor
- Internal short-circuit, thermal and safe operating area protection
- Easily adjustable to higher output voltages
- Maximum line regulation less than 0.07% V_{OUT}/V
- Maximum load regulation less than 0.01% V_{OUT}/mA
- TO-92 package

Typical Applications

Fixed Output Regulator

TL/H/7748-1

*Required if the regulator is located far from the power supply filter. A 1 μF aluminum electrolytic may be substituted.

**Required for stability. A 1 μF aluminum electrolytic may be substituted.

LMC7660/7669 Switched Capacitor Voltage Converter

General Description

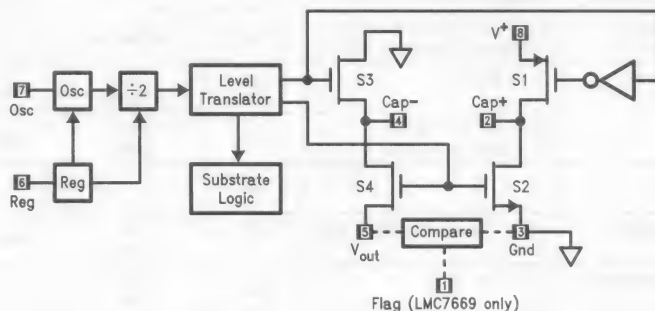

The LMC7660 and LMC7669 are CMOS voltage converters capable of converting a positive voltage in the range of +1.5V to +10V to the corresponding negative voltage of -1.5V to -10V. The LMC7660 is a pin-for-pin replacement for the popular 7660, while the LMC7669 incorporates a unique error flag to detect output fault conditions. Both converters feature: operation over full temperature and voltage range without need for an external diode, low quiescent current, and high power efficiency.

The LMC7660 uses its built-in oscillator to switch 4 power MOS switches and charge two inexpensive electrolytic capacitors. The LMC7669 requires only one additional external resistor to detect output faults.

Features

- Operation over full temperature and voltage range without an external diode
- Low supply current, 200 μ A max (7660)
- Error flag to detect output faults (7669)
- Pin-for-pin replacement for the 7660
- Wide operating range 1.5V to 10V
- 97% Voltage Conversion Efficiency
- 95% Power Conversion Efficiency
- Easy to use, only 2 external components
- Extended temperature range

Note 1: Absolute Maximum ratings indicate limits beyond which damage to the device may occur. DC and AC electrical specifications do not apply when operating the device beyond its rated operating conditions. See Note 4 for conditions.

Note 2: Connecting any input terminal to voltages greater than V^+ or less than ground may cause destructive latchup. It is recommended that no inputs from sources operating from external supplies be applied prior to "power-up" of the LMC7660 or the LMC7669.

Note 3: For operation at elevated temperature, these devices must be derated based on a thermal resistance of θ_{ja} and T_j max, $T_j = T_A + \theta_{ja} P_D$.

Note 4: Boldface numbers apply at temperature extremes. All other numbers apply at $T_A = 25^\circ C$, $V^+ = 5V$, $C_{osc} = 0$, and apply for the LMC7660 and the LMC7669 unless otherwise specified. Test circuit is shown in Figure 1.

Note 5: Guaranteed and 100% production tested.

Note 6: Guaranteed over the operating temperature range (but not 100% tested). These limits are not used to calculate outgoing quality levels.

Note 7: The LMC7660 and the LMC7669 can operate without an external diode over the full temperature and voltage range. The LMC7660 can also be used with the external diode Dx, when replacing previous 7660 designs.

Note 8: The test circuit consists of the human body model of 100 pF in series with 1500 Ω .

*Pull down resistor (LMC7669 only)

FIGURE 1. LMC7660/LMC7669 Test Circuit

Typical Performance Characteristics

TL/H/9136-4

CIRCUIT DESCRIPTION

The LMC7660 contains four large CMOS switches which are switched in a sequence to provide supply inversion $V_{out} = -V_{in}$. Energy transfer and storage are provided by two inexpensive electrolytic capacitors. Figure 2 shows how the LMC7660 can be used to generate $-V^+$ from V^+ . When switches S1 and S3 are closed, C_p charges to the supply voltage V^+ . During this time interval, switches S2 and S4 are open. After C_p charges to V^+ , S1 and S3 are opened, S2 and S4 are then closed. By connecting S2 to ground, C_p develops a voltage $-V^+/2$ on C_r . After a number of cycles C_r will be pumped to exactly $-V^+$. This transfer will be exact assuming no load on C_r , and no loss in the switches.

In the circuit of Figure 2, S1 is a P-channel device and S2, S3, and S4 are N-channel devices. Because the output is biased below ground, it is important that the p^- wells of S3 and S4 never become forward biased with respect to either their sources or drains. A substrate logic circuit guarantees that these p^- wells are always held at the proper voltage. Under all conditions S4 p^- well must be at the lowest potential in the circuit. To switch off S4, a level translator generates $V_{GS4} = 0V$, and this is accomplished by biasing the level translator from the S4 p^- well.

An internal RC oscillator and $\div 2$ circuit provide timing signals to the level translator. The built-in regulator biases the oscillator and divider to reduce power dissipation on high supply voltage. The regulator becomes active at about $V^+ = 6.5V$. Low voltage operation can be improved if the LV pin is shorted to ground for $V^+ \leq 3.5V$. For $V^+ \geq 3.5V$, the LV pin must be left open to prevent damage to the part.

The LMC7669 is identical to the LMC7660 with the exception of an error flag that warns of output fault conditions. The flag goes low when a fault pulls the output to about $-0.5V^+$. Hysteresis provides a reset to the flag when $V_{out} = -0.75V^+$. The only additional component required is a pull down resistor.

POWER EFFICIENCY AND RIPPLE

It is theoretically possible to approach 100% efficiency if the following conditions are met:

- 1) The drive circuitry consumes little power.
- 2) The power switches are matched and have low R_{on} .
- 3) The impedance of the reservoir and pump capacitors are negligibly small at the pumping frequency.

The LMC7660 closely approaches 1 and 2 above. By using a large pump capacitor C_p , the charge removed while supplying the reservoir capacitor is small compared to C_p 's total charge. Small removed charge means small changes in the pump capacitor voltage, and thus small energy loss and high efficiency. The energy loss by C_p is:

$$E = \frac{1}{2}C_p(V_1^2 - V_2^2)$$

By using a large reservoir capacitor, the output ripple can be reduced to an acceptable level. For example, if the load current is 5 mA and the accepted ripple is 200 mV, then the reservoir capacitor can omit approximately be calculated from:

$$I_s = C_r \frac{dv}{dt}$$

$$\sim C_r \times \frac{V_{\text{ripple p-p}}}{4/F_{\text{osc}}} \quad C_r = \frac{0.5 \text{ mA}}{0.5V/ms} = 10 \mu F$$

PRECAUTIONS

- 1) Do not exceed the maximum supply voltage or junction temperature.
- 2) Do not short pin 6 (LV terminal) to ground for supply voltages greater than 3.5V.
- 3) Do not short circuit the output to V^+ .
- 4) External electrolytic capacitors C_r and C_p should have their polarities connected as shown in Figure 1.

REPLACING PREVIOUS 7660 DESIGNS

To prevent destructive latchup, previous 7660 designs require a diode in series with the output when operated at elevated temperature or supply voltage. Although this prevented the latchup problem of these designs, it lowered the available output voltage and increased the output series resistance.

The National LMC7660 and LMC7669 have been designed to solve the inherent latch problem. The LMC7660 and

FIGURE 2. Idealized Voltage Converter

TL/H/9136-6

LMC7669 can operate over the entire supply voltage and temperature range without the need for an output diode. When replacing existing designs, the LMC7660 can be operated with diode Dx.

Typical Applications

Changing Oscillator Frequency

It is possible to dramatically reduce the quiescent operating current of the LMC7660/7669 by lowering the oscillator frequency. The oscillator frequency can be lowered from a nominal 10 kHz to several hundred hertz, by adding a slow-down capacitor C_{OSC} (Figure 3). As shown in the Typical Performance Curves the supply current can be lowered to the 10 μ A range. This low current drain can be extremely

useful when used in μ Power and battery back-up equipment. It must be understood that the lower operating frequency and supply current cause an increased impedance of C_r and C_p . The increased impedance, due to a lower switching rate, can be offset by raising C_r and C_p until ripple and load current requirements are met.

Synchronizing to an External Clock

Figure 4 shows an LMC7660 synchronized to an external clock. The CMOS gate overrides the internal oscillator when it is necessary to switch faster or reduce power supply interference. The external clock still passes through the $\div 2$ circuit in the 7660, so the pumping frequency will be $1/2$ the external clock frequency.

TL/H/9136-7

FIGURE 3. Reduce Supply Current by Lowering Oscillator Frequency

TL/H/9136-8

FIGURE 4. Synchronizing to an External Clock

Typical Applications (Continued)

Lowering Output Impedance

Paralleling two or more LMC7660's lowers output impedance. Each device must have its own pumping capacitor C_p , but the reservoir capacitor C_r is shared as depicted in *Figure 5*. The composite output resistance is:

$$R_{out} = \frac{R_{out \text{ of one LMC7660}}}{\text{Number of devices}}$$

Increasing Output Voltage

Stacking the LMC7660s is an easy way to produce a greater negative voltage. It should be noted that the input

current required for each stage is twice the load current on that stage as shown in *Figure 6A*. The effective output resistance is approximately the sum of the individual R_{out} values, and so only a few levels of multiplication can be used.

It is possible to generate $-15V$ from $+5V$ by connecting the second 7660's pin 8 to $+5V$ instead of ground as shown in *Figure 6B*. Note that the second 7660 sees a full $20V$ and the input supply should not be increased beyond $+5V$.

TL/H/9136-10

FIGURE 6A. Higher Voltage by Cascade

TL/H/9136-11

FIGURE 6B. Getting $-15V$ from $+5V$

Typical Applications (Continued)

Split V^+ In Half

Figure 7 is one of the more interesting applications for the LMC7660. The circuit can be used as a precision voltage divider (for very light loads), alternately it is used to generate a $\frac{1}{2}$ supply point in battery applications. In the $\frac{1}{2}$ cycle when S1 and S3 are closed, the supply voltage divides across the capacitors in a conventional way proportional to their value. In the $\frac{1}{2}$ cycle when S2 and S4 are closed, the capacitors switch from a series connection to a parallel connection. This forces the capacitors to have the same voltage; the charge redistributes to maintain precisely $V^+/2$, across C_p and C_r . In this application all devices are only $V^+/2$, and the supply voltage can be raised to 20V giving exactly 10V at V_{out} .

FIGURE 7. Split V^+ in Half

TL/H/9136-12

FIGURE 8. Positive Voltage Multiplier

TL/H/9136-13

Getting Up . . . and Down

The LMC7660 can also be used as a positive voltage multiplier. This application, shown in Figure 8, requires 2 additional diodes. During the first $\frac{1}{2}$ cycle S2 charges C_{p1} through D1; D2 is reverse biased. In the next $\frac{1}{2}$ cycle S2 is open and S1 is closed. Since C_{p1} is charged to $V^+ - V_{D1}$ and is referenced to V^+ through S1, the junction of D1 and D2 is at $V^+ + (V^+ - V_{D1})$. D1 is reverse biased in this interval. This application uses only two of the four switches in the 7660. The other two switches can be put to use in performing a negative conversion at the same time as shown in Figure 9. In the $\frac{1}{2}$ cycle that D1 is charging C_{p1} , C_{p2} is connected from ground to $-V_{out}$ via S2 and S4, and C_r2 is storing C_{p2} 's charge. In the interval that S1 and S3 are closed, C_{p1} pumps the junction of D1 and D2 above V^+ , while C_{p2} is refreshed from V^+ .

Typical Applications (Continued)

TL/H/9136-14

FIGURE 9. Combined Negative Converter and Positive Multiplier

Thermometer Spans 180°C

Using the combined negative and positive multiplier of Figure 10 with an LM35 it is possible to make a μ Power thermometer that spans a 180°C temperature range. The LM35 temperature sensor has an output sensitivity of 10 mV/°C, while drawing only 50 μ A of quiescent current. In order for the LM35 to measure negative temperatures, a pull down to a negative voltage is required. Figure 10 shows a thermometer circuit for measuring temperatures from -55°C to +125°C and requiring only two 1.5V cells. End of battery life can be extended by replacing the up converter diodes with Schottky's.

Regulating -V_{out}

It is possible to regulate the output of the LMC7660 and still maintain μ Power performance. This is done by enclosing

the LMC7660 in a loop with a LP2951. The circuit of Figure 11 will regulate V_{out} to -5V for I_L = 10 mA, and V_{in} = 6V. For V_{in} > 7V, the output stays in regulation up to I_L = 25 mA. The error flag on pin 5 of the LP2951 sets low when the regulated output at pin 4 drops by about 5%. The LP2951 can be shutdown by taking pin 3 high; the LMC7660 can be shutdown by shorting pin 7 and pin 8.

The LP2951 can be reconfigured to an adjustable type regulator, which means the LMC7660 can give a regulated output from -2.0V to -10V dependent on the resistor ratios R1 and R2, as shown in Figure 12, V_{ref} = 1.235V:

$$V_{out} = V_{ref} \left(1 + \frac{R1}{R2} \right)$$

*For lower voltage operation, use Schottky rectifiers

FIGURE 12. LMC7660 and LP2951 Make a Negative Adjustable Regulator

TL/H/9136-17

LP2950/LP2950AC/LP2950C 5V and LP2951/LP2951AC/LP2951C Adjustable Micropower Voltage Regulators

General Description

The LP2950 and LP2951 are micropower voltage regulators with very low quiescent current (75 μ A typ.) and very low dropout voltage (typ. 40 mV at light loads and 380 mV at 100 mA). They are ideally suited for use in battery-powered systems. Furthermore, the quiescent current of the LP2950/LP2951 increases only slightly in dropout, prolonging battery life.

The LP2950 in the popular 3-pin TO-92 package is pin-compatible with older 5V regulators. The 8-lead LP2951 is available in plastic, ceramic dual-in-line, or metal can packages and offers additional system functions.

One such feature is an error flag output which warns of a low output voltage, often due to falling batteries on the input. It may be used for a power-on reset. A second feature is the logic-compatible shutdown input which enables the regulator to be switched on and off. Also, the part may be pin-strapped for a 5V output or programmed from 1.24V to 29V with an external pair of resistors.

Careful design of the LP2950/LP2951 has minimized all contributions to the error budget. This includes a tight initial

tolerance (.5% typ.), extremely good load and line regulation (.05% typ.) and a very low output voltage temperature coefficient, making the part useful as a low-power voltage reference.

Features

- High accuracy 5V, guaranteed 100 mA output
- Extremely low quiescent current
- Low dropout voltage
- Extremely tight load and line regulation
- Very low temperature coefficient
- Use as Regulator or Reference
- Needs only 1 μ F for stability
- Current and Thermal Limiting

LP2951 versions only

- Error flag warns of output dropout
- Logic-controlled electronic shutdown
- Output programmable from 1.24 to 29V

Note 1: Boldface limits apply at temperature extremes.

Note 2: Unless otherwise specified all limits guaranteed for $T_J = 25^\circ C$, $V_{in} = 6V$, $I_L = 100 \mu A$ and $C_L = 1 \mu f$. Additional conditions for the 8-pin versions are Feedback tied to 5V Tap and Output tied to Output Sense ($V_{out} = 5V$) and $V_{shutdown} \leq 0.8V$.

Note 3: Guaranteed and 100% production tested.

Note 4: Guaranteed but not 100% production tested. These limits are not used to calculate outgoing AQL levels.

Note 5: Dropout Voltage is defined as the input to output differential at which the output voltage drops 100 mV below its nominal value measured at 1V differential. At very low values of programmed output voltage, the minimum input supply voltage of 2V (**2.3V over temperature**) must be taken into account.

Note 6: Comparator thresholds are expressed in terms of a voltage differential at the Feedback terminal below the nominal reference voltage measured at 6V input. To express these thresholds in terms of output voltage change, multiply by the error amplifier gain $= V_{out}/V_{ref} = (R1 + R2)/R2$. For example, at a programmed output voltage of 5V, the Error output is guaranteed to go low when the output drops by $95 mV \times 5V/1.235V = 384 mV$. Thresholds remain constant as a percent of V_{out} as V_{out} is varied, with the dropout warning occurring at typically 5% below nominal, 7.5% guaranteed.

Note 7: $V_{ref} \leq V_{out} \leq (V_{in} - 1V)$, $2.3V \leq V_{in} \leq 30V$, $100 \mu A \leq I_L \leq 100 mA$, $T_J \leq T_{JMAX}$.

Note 8: The junction-to-ambient thermal resistance of the TO-92 package is $180^\circ C/W$ with 0.4" leads and $160^\circ C/W$ with 0.25" leads to a PC board. The thermal resistance of the 8-pin DIP packages is $105^\circ C/W$ for the molded plastic (N) and $130^\circ C/W$ for the cerdip (J) junction to ambient when soldered directly to a PC board. Thermal resistance for the metal can (H) is $160^\circ C/W$ junction to ambient and $20^\circ C/W$ junction to case. Junction to ambient thermal resistance for the S.O. (M) package is $160^\circ C/W$.

Note 9: May exceed input supply voltage.

Note 10: When used in dual-supply systems where the output terminal sees loads returned to a negative supply, the output voltage should be diode-clamped to ground.

Note 11: $V_{shutdown} \geq 2V$, $V_{in} \leq 30V$, $V_{out} = 0$, Feedback pin tied 5V Tap.

Note 12: Output or reference voltage temperature coefficient is defined as the worst case voltage change divided by the total temperature range.

Note 13: Thermal regulation is defined as the change in output voltage at a time T after a change in power dissipation is applied, excluding load or line regulation effects. Specifications are for a 50 mA load pulse at $V_{in} = 30V$ (1.25W pulse) for $T = 10 ms$.

Note 14: Regulation is measured at constant junction temperature, using pulse testing with a low duty cycle. Changes in output voltage due to heating effects are covered under the specification for thermal regulation.

Note 15: Line regulation for the LP2951 is tested at $150^\circ C$ for $I_L = 1 mA$. For $I_L = 100 \mu A$ and $T_J = 125^\circ C$, line regulation is guaranteed by design to 0.2%. See Typical Performance Characteristics for line regulation versus temperature and load current.

Application Hints

EXTERNAL CAPACITORS

A 1.0 μF (or greater) capacitor is required between the LP2950/LP2951 output and ground for stability. Without this capacitor the part will oscillate. Most types of tantalum or aluminum electrolytics work fine here; even film types work but are not recommended for reasons of cost. Many aluminum electrolytics have electrolytes that freeze at about -30°C , so solid tantalums are recommended for operation below -25°C . The important parameters of the capacitor are an ESR of about 5 Ω or less and a resonant frequency above 500 kHz. The value of this capacitor may be increased without limit.

At lower values of output current, less output capacitance is required for stability. The capacitor can be reduced to 0.33 μF for currents below 10 mA or 0.1 μF for currents below 1 mA. Using the 8-Pin versions at voltages below 5V runs

the error amplifier at lower gains so that more output capacitance is needed. For the worst-case situation of a 100 mA load at 1.23V output (Output shorted to Feedback) a 3.3 μF (or greater) capacitor should be used.

Unlike many other regulators, the L2950 will remain stable and in regulation with no load in addition to the internal voltage divider. This is especially important in CMOS RAM keep-alive applications. When setting the output voltage of the LP2951 version with external resistors, a minimum load of 1 μA is recommended.

A 0.1 μF capacitor should be placed from the LP2950/LP2951 input to ground if there is more than 10 inches of wire between the input and the AC filter capacitor or if a battery is used as the input.

Stray capacitance to the LP2951 Feedback terminal (pin 7) can cause instability. This may especially be a problem

Application Hints (Continued)

when using high value external resistors to set the output voltage. Adding a 100 pF capacitor between Output and Feedback and increasing the output capacitor to at least 3.3 μ F will fix this problem.

ERROR DETECTION COMPARATOR OUTPUT

The comparator produces a logic low output whenever the LP2951 output falls out of regulation by more than approximately 5%. This figure is the comparator's built-in offset of about 60 mV divided by the 1.235 reference voltage. (Refer to the block diagram in the front of the datasheet.) This trip level remains "5% below normal" regardless of the programmed output voltage of the 2951. For example, the error flag trip level is typically 4.75V for a 5V output or 11.4V for a 12V output. The out of regulation condition may be due either to low input voltage, current limiting, or thermal limiting.

Figure 1 below gives a timing diagram depicting the ERROR signal and the regulated output voltage as the LP2951 input is ramped up and down. The ERROR signal becomes valid (low) at about 1.3V input. It goes high at about 5V input (the input voltage at which $V_{OUT} = 4.75$). Since the LP2951's dropout voltage is load-dependent (see curve in typical performance characteristics), the input voltage trip point (about 5V) will vary with the load current. The output voltage trip point (approx. 4.75V) does not vary with load.

The error comparator has an open-collector output which requires an external pullup resistor. This resistor may be returned to the 5V output or some other supply voltage depending on system requirements. In determining a value for this resistor, note that while the output is rated to sink 400 μ A, this sink current adds to battery drain in a low battery condition. Suggested values range from 100k to 1 M Ω . The resistor is not required if this output is unused.

PROGRAMMING THE OUTPUT VOLTAGE (LP2951)

The LP2951 may be pin-strapped for 5V using its internal voltage divider by tying Pin 1 (output) to Pin 2 (sense) and Pin 7 (feedback) to Pin 6 (5V Tap). Alternatively, it may be programmed for any output voltage between its 1.235V reference and its 30V maximum rating. As seen in Figure 2, an external pair of resistors is required.

The complete equation for the output voltage is

$$V_{OUT} = V_{REF} \cdot \left(1 + \frac{R_1}{R_2}\right) + I_{FB}R_1$$

where V_{REF} is the nominal 1.235 reference voltage and I_{FB} is the feedback pin bias current, nominally -20 nA. The

minimum recommended load current of 1 μ A forces an upper limit of 1.2 M Ω on the value of R_2 , if the regulator must work with no load (a condition often found in CMOS in standby). I_{FB} will produce a 2% typical error in V_{OUT} which may be eliminated at room temperature by trimming R_1 . For better accuracy, choosing $R_2 = 100k$ reduces this error to 0.17% while increasing the resistor program current to 12 μ A. Since the LP2951 typically draws 60 μ A at no load with Pin 2 open-circuited, this is a small price to pay.

REDUCING OUTPUT NOISE

In reference applications it may be advantageous to reduce the AC noise present at the output. One method is to reduce the regulator bandwidth by increasing the size of the output capacitor. This is the only way noise can be reduced on the 3 lead LP2950 but is relatively inefficient, as increasing the capacitor from 1 μ F to 220 μ F only decreases the noise from 430 μ V to 160 μ V rms for a 100 kHz bandwidth at 5V output.

Noise can be reduced fourfold by a bypass capacitor across R_1 , since it reduces the high frequency gain from 4 to unity. Pick

$$C_{BYPASS} \approx \frac{1}{2\pi R_1 \cdot 200 \text{ Hz}}$$

or about 0.01 μ F. When doing this, the output capacitor must be increased to 3.3 μ F to maintain stability. These changes reduce the output noise from 430 μ V to 100 μ V rms for a 100 kHz bandwidth at 5V output. With the bypass capacitor added, noise no longer scales with output voltage so that improvements are more dramatic at higher output voltages.

Operational Amplifiers Definition of Terms

Bandwidth: That frequency at which the voltage gain is reduced to $1/\sqrt{2}$ times the low frequency value.

Common-Mode Rejection Ratio: The ratio of the input common-mode voltage range to the peak-to-peak change in input offset voltage over this range.

Harmonic Distortion: That percentage of harmonic distortion being defined as one-hundred times the ratio of the root-mean-square (rms) sum of the harmonics to the fundamental. % harmonic distortion =

$$\frac{(V_2^2 + V_3^2 + V_4^2 + \dots)^{1/2}}{V_1} (100\%)$$

where V_1 is the rms amplitude of the fundamental and V_2 , V_3 , V_4 , ... are the rms amplitudes of the individual harmonics.

Input Bias Current: The average of the two input currents.

Input Common-Mode Voltage Range: The range of voltages on the input terminals for which the amplifier is operational. Note that the specifications are not guaranteed over the full common-mode voltage range unless specifically stated.

Input Impedance: The ratio of input voltage to input current under the stated conditions for source resistance (R_S) and load resistance (R_L).

Input Offset Current: The difference in the currents into the two input terminals when the output is at zero.

Input Offset Voltage: That voltage which must be applied between the input terminals through two equal resistances to obtain zero output voltage.

Input Resistance: The ratio of the change in input voltage to the change in input current on either input with the other grounded.

Input Voltage Range: The range of voltages on the input terminals for which the amplifier operates within specifications.

Large-Signal Voltage Gain: The ratio of the output voltage swing to the change in input voltage required to drive the output from zero to this voltage.

Output Impedance: The ratio of output voltage to output current under the stated conditions for source resistance (R_S) and load resistance (R_L).

Output Resistance: The small signal resistance seen at the output with the output voltage near zero.

Output Voltage Swing: The peak output voltage swing, referred to zero, that can be obtained without clipping.

Offset Voltage Temperature Drift: The average drift rate of offset voltage for a thermal variation from room temperature to the indicated temperature extreme.

Power Supply Rejection: The ratio of the change in input offset voltage to the change in power supply voltages producing it.

Settling Time: The time between the initiation of the input step function and the time when the output voltage has settled to within a specified error band of the final output voltage.

Slew Rate: The internally-limited rate of change in output voltage with a large-amplitude step function applied to the input.

Supply Current: The current required from the power supply to operate the amplifier with no load and the output midway between the supplies.

Transient Response: The closed-loop step-function response of the amplifier under small-signal conditions.

Unity Gain Bandwidth: The frequency range from dc to the frequency where the amplifier open loop gain rolls off to one.

Voltage Gain: The ratio of output voltage to input voltage under the stated conditions for source resistance (R_S) and load resistance (R_L).

LF147/LF347/LF347B Wide Bandwidth Quad JFET Input Operational Amplifiers

General Description

The LF147 is a low cost, high speed quad JFET input operational amplifier with an internally trimmed input offset voltage (BI-FET IIT™ technology). The device requires a low supply current and yet maintains a large gain bandwidth product and a fast slew rate. In addition, well matched high voltage JFET input devices provide very low input bias and offset currents. The LF147 is pin compatible with the standard LM148. This feature allows designers to immediately upgrade the overall performance of existing LF148 and LM124 designs.

The LF147 may be used in applications such as high speed integrators, fast D/A converters, sample-and-hold circuits and many other circuits requiring low input offset voltage, low input bias current, high input impedance, high slew rate and wide bandwidth. The device has low noise and offset voltage drift.

Features

- Internally trimmed offset voltage 2 mV
- Low input bias current 50 pA
- Low input noise current 0.01 pA/√Hz
- Wide gain bandwidth 4 MHz
- High slew rate 13 V/μs
- Low supply current 7.2 mA
- High input impedance 10¹²Ω
- Low total harmonic distortion $A_V = 10$, $R_L 10k$, $V_O = 20$ Vp-p, BW = 20 Hz – 20 kHz <0.02%
- Low 1/f noise corner 50 Hz
- Fast settling time to 0.01% 2 μs

AC Electrical Characteristics (Note 5)

Symbol	Parameter	Conditions	LF147			LF347B			LF347			Units
			Min	Typ	Max	Min	Typ	Max	Min	Typ	Max	
	Amplifier to Amplifier Coupling	$T_A = 25^\circ\text{C}$, $f = 1\text{ Hz} - 20\text{ kHz}$ (Input Referred)		-120			-120			-120		dB
SR	Slew Rate	$V_S = \pm 15\text{V}$, $T_A = 25^\circ\text{C}$		13			13			13		$\text{V}/\mu\text{s}$
GBW	Gain-Bandwidth Product	$V_S = \pm 15\text{V}$, $T_A = 25^\circ\text{C}$		4			4			4		MHz
e_n	Equivalent Input Noise Voltage	$T_A = 25^\circ\text{C}$, $R_S = 100\Omega$, $f = 1000\text{ Hz}$		20			20			20		$\text{nV}/\sqrt{\text{Hz}}$
i_n	Equivalent Input Noise Current	$T_J = 25^\circ\text{C}$, $f = 1000\text{ Hz}$		0.01			0.01			0.01		$\text{pA}/\sqrt{\text{Hz}}$

Note 1: Unless otherwise specified the absolute maximum negative input voltage is equal to the negative power supply voltage.

Note 2: Any of the amplifier outputs can be shorted to ground indefinitely, however, more than one should not be simultaneously shorted as the maximum junction temperature will be exceeded.

Note 3: For operating at elevated temperature, these devices must be derated based on a thermal resistance of θ_{JA} .

Note 4: The LF147 is available in the military temperature range $-55^\circ\text{C} \leq T_A \leq 125^\circ\text{C}$, while the LF347B and the LF347 are available in the commercial temperature range $0^\circ\text{C} \leq T_A \leq 70^\circ\text{C}$. Junction temperature can rise to $T_J \text{ max} = 25^\circ\text{C}$.

Note 5: Unless otherwise specified the specifications apply over the full temperature range and for $V_S = \pm 20\text{V}$ for the LF147 and for $V_S = \pm 15\text{V}$ for the LF347B/LF347. V_{OS} , I_B , and I_{OS} are measured at $V_{CM} = 0$.

Note 6: The input bias currents are junction leakage currents which approximately double for every 10°C increase in the junction temperature, T_J . Due to limited production test time, the input bias currents measured are correlated to junction temperature. In normal operation the junction temperature rises above the ambient temperature as a result of internal power dissipation, P_D . $T_J = T_A + \theta_{JA} P_D$ where θ_{JA} is the thermal resistance from junction to ambient. Use of a heat sink is recommended if input bias current is to be kept to a minimum.

Note 7: Supply voltage rejection ratio is measured for both supply magnitudes increasing or decreasing simultaneously in accordance with common practice from $V_S = \pm 5\text{V}$ to $\pm 15\text{V}$ for the LF347 and LF347B and from $V_S = \pm 20\text{V}$ to $\pm 5\text{V}$ for the LF147.

Note 8: Refer to RETS147X for LF147D and LF147J military specifications.

Note 9: Max. Power Dissipation is defined by the package characteristics. Operating the part near the Max. Power Dissipation may cause the part to operate outside guaranteed limits.

Application Hints

The LF147 is an op amp with an internally trimmed input offset voltage and JFET input devices (BI-FET IITM). These JFETs have large reverse breakdown voltages from gate to source and drain eliminating the need for clamps across the inputs. Therefore, large differential input voltages can easily be accommodated without a large increase in input current. The maximum differential input voltage is independent of the supply voltages. However, neither of the input voltages

should be allowed to exceed the negative supply as this will cause large currents to flow which can result in a destroyed unit.

Exceeding the negative common-mode limit on either input will force the output to a high state, potentially causing a reversal of phase to the output. Exceeding the negative common-mode limit on both inputs will force the amplifier

Application Hints (Continued)

output to a high state. In neither case does a latch occur since raising the input back within the common-mode range again puts the input stage and thus the amplifier in a normal operating mode.

Exceeding the positive common-mode limit on a single input will not change the phase of the output; however, if both inputs exceed the limit, the output of the amplifier will be forced to a high state.

The amplifiers will operate with a common-mode input voltage equal to the positive supply; however, the gain bandwidth and slew rate may be decreased in this condition. When the negative common-mode voltage swings to within 3V of the negative supply, an increase in input offset voltage may occur.

Each amplifier is individually biased by a zener reference which allows normal circuit operation on $\pm 4.5V$ power supplies. Supply voltages less than these may result in lower gain bandwidth and slew rate.

The LF147 will drive a $2\text{ k}\Omega$ load resistance to $\pm 10V$ over the full temperature range. If the amplifier is forced to drive heavier load currents, however, an increase in input offset voltage may occur on the negative voltage swing and finally reach an active current limit on both positive and negative swings.

Precautions should be taken to ensure that the power supply for the integrated circuit never becomes reversed in polarity or that the unit is not inadvertently installed back-

wards in a socket as an unlimited current surge through the resulting forward diode within the IC could cause fusing of the internal conductors and result in a destroyed unit.

Because these amplifiers are JFET rather than MOSFET input op amps they do not require special handling.

As with most amplifiers, care should be taken with lead dress, component placement and supply decoupling in order to ensure stability. For example, resistors from the output to an input should be placed with the body close to the input to minimize "pick-up" and maximize the frequency of the feedback pole by minimizing the capacitance from the input to ground.

A feedback pole is created when the feedback around any amplifier is resistive. The parallel resistance and capacitance from the input of the device (usually the inverting input) to AC ground set the frequency of the pole. In many instances the frequency of this pole is much greater than the expected 3 dB frequency of the closed loop gain and consequently there is negligible effect on stability margin. However, if the feedback pole is less than approximately 6 times the expected 3 dB frequency a lead capacitor should be placed from the output to the input of the op amp. The value of the added capacitor should be such that the RC time constant of this capacitor and the resistance it parallels is greater than or equal to the original feedback pole time constant.

LF155/LF156/LF157 Series Monolithic JFET Input Operational Amplifiers

**LF155, LF155A, LF255, LF355, LF355A,
LF355B Low Supply Current
LF156, LF156A, LF256, LF356, LF356A,
LF356B Wide Band
LF157, LF157A, LF257, LF357, LF357A,
LF357B Wide Band Decompensated ($A_{V_{MIN}} = 5$)**

General Description

These are the first monolithic JFET input operational amplifiers to incorporate well matched, high voltage JFETs on the same chip with standard bipolar transistors (BI-FET™ Technology). These amplifiers feature low input bias and offset currents, low offset voltage and offset voltage drift, coupled with offset adjust which does not degrade drift or common-mode rejection. The devices are also designed for high slew rate, wide bandwidth, extremely fast settling time, low voltage and current noise and a low $1/f$ noise corner.

Advantages

- Replace expensive hybrid and module FET op amps
- Rugged JFETs allow blow-out free handling compared with MOSFET input devices
- Excellent for low noise applications using either high or low source impedance—very low $1/f$ corner
- Offset adjust does not degrade drift or common-mode rejection as in most monolithic amplifiers
- New output stage allows use of large capacitive loads (10,000 pF) without stability problems
- Internal compensation and large differential input voltage capability

Applications

- Precision high speed integrators
- Fast D/A and A/D converters
- High impedance buffers
- Wideband, low noise, low drift amplifiers
- Logarithmic amplifiers

- Photocell amplifiers
- Sample and Hold circuits

Common Features

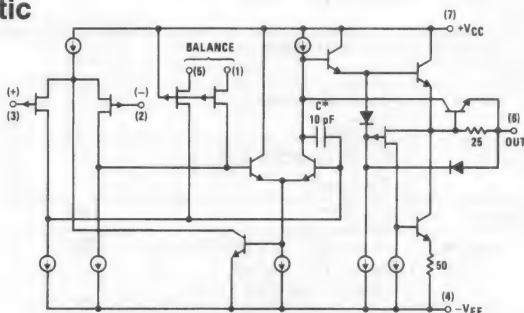

(LF155A, LF156A, LF157A)

- Low input bias current 30 pA
- Low Input Offset Current 3 pA
- High input impedance $10^{12} \Omega$
- Low input offset voltage 1 mV
- Low input offset voltage temp. drift $3 \mu V/^{\circ}C$
- Low input noise current $0.01 \text{ pA}/\sqrt{\text{Hz}}$
- High common-mode rejection ratio 100 dB
- Large dc voltage gain 106 dB

Uncommon Features

	LF155A	LF156A	LF157A ($A_V = 5$)	Units
■ Extremely fast settling time to 0.01%	4	1.5	1.5	μs
■ Fast slew rate	5	12	50	$V/\mu s$
■ Wide gain bandwidth	2.5	5	20	MHz
■ Low input noise voltage	20	12	12	$nV/\sqrt{\text{Hz}}$

Simplified Schematic

Notes for Electrical Characteristics

Note 1: The maximum power dissipation for these devices must be derated at elevated temperatures and is dictated by $T_{J\text{MAX}}$, θ_{JA} , and the ambient temperature, T_A . The maximum available power dissipation at any temperature is $P_d = (T_{J\text{MAX}} - T_A) / \theta_{JA}$ or the 25°C $P_{d\text{MAX}}$, whichever is less.

Note 2: Unless otherwise specified the absolute maximum negative input voltage is equal to the negative power supply voltage.

Note 3: Unless otherwise stated, these test conditions apply:

	LF155A/6A/7A LF155//6/7	LF255//6/7	LF355A/6A/7A	LF355B/6B/7B	LF355//6/7
Supply Voltage, V_S	$\pm 15\text{V} \leq V_S \leq \pm 20\text{V}$	$\pm 15\text{V} \leq V_S \leq \pm 20\text{V}$	$\pm 15\text{V} \leq V_S \leq \pm 18\text{V}$	$\pm 15\text{V} \leq V_S \leq \pm 20\text{V}$	$V_S = \pm 15\text{V}$
T_A	$-55^{\circ}\text{C} \leq T_A \leq +125^{\circ}\text{C}$	$-25^{\circ}\text{C} \leq T_A \leq +85^{\circ}\text{C}$	$0^{\circ}\text{C} \leq T_A \leq +70^{\circ}\text{C}$	$0^{\circ}\text{C} \leq T_A \leq +70^{\circ}\text{C}$	$0^{\circ}\text{C} \leq T_A \leq +70^{\circ}\text{C}$
T_{HIGH}	$+125^{\circ}\text{C}$	$+85^{\circ}\text{C}$	$+70^{\circ}\text{C}$	$+70^{\circ}\text{C}$	$+70^{\circ}\text{C}$

and V_{OS} , I_B and I_{OS} are measured at $V_{CM} = 0$.

Note 4: The Temperature Coefficient of the adjusted input offset voltage changes only a small amount ($0.5\mu\text{V}/^{\circ}\text{C}$ typically) for each mV of adjustment from its original unadjusted value. Common-mode rejection and open loop voltage gain are also unaffected by offset adjustment.

Note 5: The input bias currents are junction leakage currents which approximately double for every 10°C increase in the junction temperature, T_J . Due to limited production test time, the input bias currents measured are correlated to junction temperature. In normal operation the junction temperature rises above the ambient temperature as a result of internal power dissipation, P_d . $T_J = T_A + \theta_{JA} P_d$ where θ_{JA} is the thermal resistance from junction to ambient. Use of a heat sink is recommended if input bias current is to be kept to a minimum.

Note 6: Supply Voltage Rejection is measured for both supply magnitudes increasing or decreasing simultaneously, in accordance with common practice.

Note 7: Settling time is defined here, for a unity gain inverter connection using $2\text{ k}\Omega$ resistors for the LF155/6. It is the time required for the error voltage (the voltage at the inverting input pin on the amplifier) to settle to within 0.01% of its final value from the time a 10V step input is applied to the inverter. For the LF157, $A_V = -5$, the feedback resistor from output to input is $2\text{ k}\Omega$ and the output step is 10V (See Settling Time Test Circuit).

Note 8: Refer to RETS155AX for LF155A, RETS155X for LF155, RETSF156AX for LF156A, RETS156X for LF156, RETS157A for LF157A and RETS157X for LF157 military specifications.

Note 9: Max. Power Dissipation is defined by the package characteristics. Operating the part near the Max. Power Dissipation may cause the part to operate outside guaranteed limits.

Application Hints

The LF155/6/7 series are op amps with JFET input devices. These JFETs have large reverse breakdown voltages from gate to source and drain eliminating the need for clamps across the inputs. Therefore large differential input voltages can easily be accommodated without a large increase in input current. The maximum differential input voltage is independent of the supply voltages. However, neither of the input voltages should be allowed to exceed the negative supply as this will cause large currents to flow which can result in a destroyed unit.

Exceeding the negative common-mode limit on either input will force the output to a high state, potentially causing a reversal of phase to the output. Exceeding the negative common-mode limit on both inputs will force the amplifier output to a high state. In neither case does a latch occur since raising the input back within the common-mode range again puts the input stage and thus the amplifier in a normal operating mode.

Exceeding the positive common-mode limit on a single input will not change the phase of the output however, if both inputs exceed the limit, the output of the amplifier will be forced to a high state.

These amplifiers will operate with the common-mode input voltage equal to the positive supply. In fact, the common-mode voltage can exceed the positive supply by approximately 100 mV independent of supply voltage and over the full operating temperature range. The positive supply can therefore be used as a reference on an input as, for example, in a supply current monitor and/or limiter.

Precautions should be taken to ensure that the power supply for the integrated circuit never becomes reversed in

polarity or that the unit is not inadvertently installed backwards in a socket as an unlimited current surge through the resulting forward diode within the IC could cause fusing of the internal conductors and result in a destroyed unit.

Because these amplifiers are JFET rather than MOSFET input op amps they do not require special handling.

All of the bias currents in these amplifiers are set by FET current sources. The drain currents for the amplifiers are therefore essentially independent of supply voltage.

As with most amplifiers, care should be taken with lead dress, component placement and supply decoupling in order to ensure stability. For example, resistors from the output to an input should be placed with the body close to the input to minimize "pickup" and maximize the frequency of the feedback pole by minimizing the capacitance from the input to ground.

A feedback pole is created when the feedback around any amplifier is resistive. The parallel resistance and capacitance from the input of the device (usually the inverting input) to ac ground set the frequency of the pole. In many instances the frequency of this pole is much greater than the expected 3 dB frequency of the closed loop gain and consequently there is negligible effect on stability margin. However, if the feedback pole is less than approximately six times the expected 3 dB frequency a lead capacitor should be placed from the output to the input of the op amp. The value of the added capacitor should be such that the RC time constant of this capacitor and the resistance it parallels is greater than or equal to the original feedback pole time constant.

Typical Circuit Connections

V_{OS} Adjustment

- V_{OS} is adjusted with a 25k potentiometer
- The potentiometer wiper is connected to V⁺
- For potentiometers with temperature coefficient of 100 ppm/°C or less the additional drift with adjust is $\approx 0.5 \mu\text{V}/^\circ\text{C}/\text{mV}$ of adjustment
- Typical overall drift: $5 \mu\text{V}/^\circ\text{C} \pm (0.5 \mu\text{V}/^\circ\text{C}/\text{mV}$ of adj.)

Driving Capacitive Loads

*LF155/6 R=5k
LF157 R=1.25k

Due to a unique output stage design, these amplifiers have the ability to drive large capacitive loads and still maintain stability. $C_{L(\text{MAX})} \approx 0.01 \mu\text{F}$.

Overshoot $\leq 20\%$

Settling time (t_0) $\approx 5 \mu\text{s}$

LF157. A Large Power BW Amplifier

TL/H/5648-15
For distortion $\leq 1\%$ and a 20 Vp-p V_{OUT} swing, power bandwidth is: 500 kHz.

Typical Applications

Settling Time Test Circuit

- Settling time is tested with the LF155/6 connected as unity gain inverter and LF157 connected for $A_V = -5$
- FET used to isolate the probe capacitance
- Output = 10V step
- $A_V = -5$ for LF157

TL/H/5646-16

Large Signal inverter Output, V_{OUT} (from Settling Time Circuit)

TL/H/5646-17

TL/H/5646-18

TL/H/5646-19

Low Drift Adjustable Voltage Reference

TL/H/5646-20

- $\Delta V_{OUT}/\Delta T = \pm 0.002\%/^{\circ}\text{C}$
- All resistors and potentiometers should be wire-wound
- P1: drift adjust
- P2: V_{OUT} adjust
- Use LF155 for
 - Low I_g
 - Low drift
 - Low supply current

Typical Applications (Continued)

Fast Logarithmic Converter

TL/H/5646-21

$$|V_{OUT}| = \left[1 + \frac{R_2}{R_T} \right] \frac{kT}{q} \ln V_i \left[\frac{R_f}{V_{REF} R_i} \right] = \log V_i \frac{1}{R_i I_f} R_2 = 15.7k, R_T = 1k, 0.3\%/^{\circ}C \text{ (for temperature compensation)}$$

- Dynamic range: $100 \mu A \leq I_i \leq 1 \text{ mA}$ (5 decades), $|V_O| = 1V/\text{decade}$
- Transient response: $3 \mu s$ for $\Delta I_i = 1 \text{ decade}$
- C1, C2, R2, R3: added dynamic compensation
- V_{OS} adjust the LF156 to minimize quiescent error
- R_T : Tel Labs type Q81 + $0.3\%/^{\circ}C$

Precision Current Monitor

TL/H/5646-31

- $V_O = 5 R_1/R_2$ (V/mA of I_S)
- R1, R2, R3: 0.1% resistors
- Use LF155 for
 - Common-mode range to supply range
 - Low I_S
 - Low V_{OS}
 - Low Supply Current

8-Bit D/A Converter with Symmetrical Offset Binary Operation

TL/H/5646-32

- R1, R2 should be matched within $\pm 0.05\%$
- Full-scale response time: $3 \mu s$

E_O	B1	B2	B3	B4	B5	B6	B7	B8	Comments
+9.920	1	1	1	1	1	1	1	1	Positive Full-Scale
+0.040	1	0	0	0	0	0	0	0	(+) Zero-Scale
-0.040	0	1	1	1	1	1	1	1	(-) Zero-Scale
-9.920	0	0	0	0	0	0	0	0	Negative Full-Scale

Typical Applications (Continued)

Wide BW Low Noise, Low Drift Amplifier

- Power BW: $f_{MAX} = \frac{S_T}{2\pi V_P} \approx 240 \text{ kHz}$
- Parasitic input capacitance $C1 \approx (3 \text{ pF for LF155, LF156 and LF157 plus any additional layout capacitance})$ interacts with feedback elements and creates undesirable high frequency pole. To compensate add $C2$ such that: $R2C2 \approx R1C1$.

Boosting the LF156 with a Current Amplifier

- $I_{OUT(MAX)} \approx 150 \text{ mA}$ (will drive $R_L \geq 100 \Omega$)
- $\frac{\Delta V_{OUT}}{\Delta T} = \frac{0.15}{10^{-2}} \text{ V}/\mu\text{s}$ (with C_L shown)
- No additional phase shift added by the current amplifier

3 Decades VCO

TL/H/5646-24

$$f = \frac{V_C (R8 + R7)}{(8 V_{PU} R8 R1) C}$$

$0 \leq V_C \leq 30 \text{ V}, 10 \text{ Hz} \leq f \leq 10 \text{ kHz}$
 $R1, R4$ matched. Linearity 0.1% over 2 decades.

Isolating Large Capacitive Loads

- Overshoot 6%
- $t_s 10 \mu\text{s}$
- When driving large C_L , the V_{OUT} slew rate determined by C_L and $I_{OUT(MAX)}$:

$$\frac{\Delta V_{OUT}}{\Delta T} = \frac{I_{OUT}}{C_L} \approx \frac{0.02}{0.5} \text{ V}/\mu\text{s} = 0.04 \text{ V}/\mu\text{s} \text{ (with } C_L \text{ shown)}$$

TL/H/5646-22

Low Drift Peak Detector

TL/H/5646

- By adding $D1$ and R_f , $V_{D1} = 0$ during hold mode. Leakage of $D2$ provided by feedback path through R_f .
- Leakage of circuit is essentially I_b (LF155, LF156) plus capacitor leakage of C_p .
- Diode $D3$ clamps V_{OUT} (A1) to $V_{IN} - V_{D3}$ to improve speed and to limit reverse bias of $D2$.
- Maximum input frequency should be $< < \frac{1}{2\pi R_f C_{D2}}$ where C_{D2} is the shunt capacitance of $D2$.

Non-Inverting Unity Gain Operation for LF157

$$R1C \geq \frac{1}{(2\pi) (5 \text{ MHz})}$$

$$R1 = \frac{R2 + R_S}{4}$$

$$A_V(DC) = 1$$

$$f_{-3 \text{ dB}} \approx 5 \text{ MHz}$$

Inverting Unity Gain for LF157

$$R1C \geq \frac{1}{(2\pi) (5 \text{ MHz})}$$

$$R1 = \frac{R2}{4}$$

$$A_V(DC) = -1$$

$$f_{-3 \text{ dB}} \approx 5 \text{ MHz}$$

TL/H/5646-25

Typical Applications (Continued)

High Impedance, Low Drift Instrumentation Amplifier

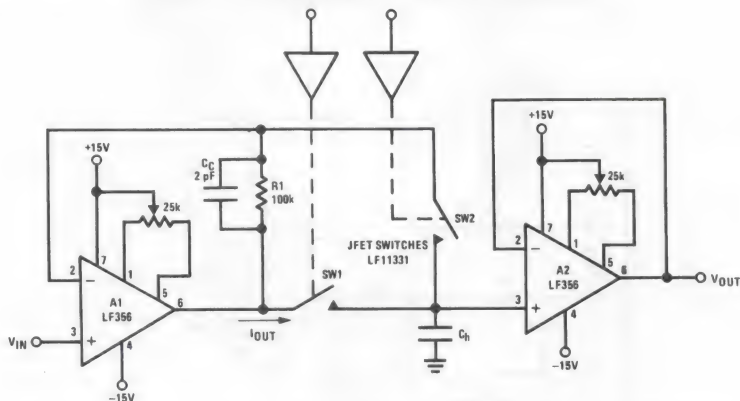

TL/H/5646-26

- $$V_{OUT} = \frac{R_3}{R} \left[\frac{2R_2}{R_1} + 1 \right] \Delta V, V^- + 2V \leq V_{IN \text{ common-mode}} \leq V^+$$
- System V_{OS} adjusted via A2 V_{OS} adjust
- Trim R3 to boost up CMRR to 120 dB. Instrumentation amplifier resistor array recommended for best accuracy and lowest drift

Typical Applications (Continued)

Fast Sample and Hold

TL/H/5646-33

- Both amplifiers (A1, A2) have feedback loops individually closed with stable responses (overshoot negligible)
- Acquisition time T_A , estimated by:

$$T_A \approx \left[\frac{2R_{ON} V_{IN} C_h}{S_r} \right]^{1/2} \text{ provided that:}$$

$$V_{IN} < 2\pi S_r R_{ON} C_h \text{ and } T_A > \frac{V_{IN} C_h}{I_{OUT(MAX)}}, R_{ON} \text{ is of SW1}$$

$$\text{If inequality not satisfied: } T_A \approx \frac{V_{IN} C_h}{20 \text{ mA}}$$

- LF156 develops full S_r output capability for $V_{IN} \geq 1V$
- Addition of SW2 improves accuracy by putting the voltage drop across SW1 inside the feedback loop
- Overall accuracy of system determined by the accuracy of both amplifiers, A1 and A2

High Accuracy Sample and Hold

TL/H/5646-27

- By closing the loop through A2, the V_{OUT} accuracy will be determined uniquely by A1. No V_{OS} adjust required for A2.
- T_A can be estimated by same considerations as previously but, because of the added propagation delay in the feedback loop (A2) the overshoot is not negligible.
- Overall system slower than fast sample and hold
- R1, C_C : additional compensation
- Use LF156 for
 - Fast settling time
 - Low V_{OS}

Typical Applications (Continued)

High Q Band Pass Filter

TL/H/5646-28

- By adding positive feedback (R2) Q increases to 40
- $f_{BP} = 100 \text{ kHz}$

$$\frac{V_{OUT}}{V_{IN}} = 10\sqrt{Q}$$

- Clean layout recommended
- Response to a 1 Vp-p tone burst: 300 μs

High Q Notch Filter

TL/H/5646-34

- $2R1 = R = 10 \text{ M}\Omega$
- $2C = C1 = 300 \text{ pF}$
- Capacitors should be matched to obtain high Q
- $f_{NOTCH} = 120 \text{ Hz}$, notch = -55 dB, $Q > 100$
- Use LF155 for
 - Low I_B
 - Low supply current

LF351 Wide Bandwidth JFET Input Operational Amplifier

General Description

The LF351 is a low cost high speed JFET input operational amplifier with an internally trimmed input offset voltage (BI-FET IITM technology). The device requires a low supply current and yet maintains a large gain bandwidth product and a fast slew rate. In addition, well matched high voltage JFET input devices provide very low input bias and offset currents. The LF351 is pin compatible with the standard LM741 and uses the same offset voltage adjustment circuitry. This feature allows designers to immediately upgrade the overall performance of existing LM741 designs.

The LF351 may be used in applications such as high speed integrators, fast D/A converters, sample-and-hold circuits and many other circuits requiring low input offset voltage, low input bias current, high input impedance, high slew rate and wide bandwidth. The device has low noise and offset voltage drift, but for applications where these requirements are critical, the LF356 is recommended. If maximum supply

current is important, however, the LF351 is the better choice.

Features

■ Internally trimmed offset voltage	10 mV
■ Low input bias current	50 pA
■ Low input noise voltage	25 nV/√Hz
■ Low input noise current	0.01 pA/√Hz
■ Wide gain bandwidth	4 MHz
■ High slew rate	13 V/μs
■ Low supply current	1.8 mA
■ High input impedance	10 ¹² Ω
■ Low total harmonic distortion $A_V = 10$, $R_L = 10k$, $V_O = 20$ Vp-p, BW = 20 Hz–20 kHz	< 0.02%
■ Low 1/f noise corner	50 Hz
■ Fast settling time to 0.01%	2 μs

AC Electrical Characteristics (Note 3)

Symbol	Parameter	Conditions	LF351			Units
			Min	Typ	Max	
SR	Slew Rate	$V_S = \pm 15V, T_A = 25^{\circ}C$		13		$V/\mu s$
GBW	Gain Bandwidth Product	$V_S = \pm 15V, T_A = 25^{\circ}C$		4		MHz
e_n	Equivalent Input Noise Voltage	$T_A = 25^{\circ}C, R_S = 100\Omega, f = 1000\text{ Hz}$		25		nV/\sqrt{Hz}
i_n	Equivalent Input Noise Current	$T_j = 25^{\circ}C, f = 1000\text{ Hz}$		0.01		pA/\sqrt{Hz}

Note 1: For operating at elevated temperature, the device must be derated based on the thermal resistance, θ_{JA} .

Note 2: Unless otherwise specified the absolute maximum negative input voltage is equal to the negative power supply voltage.

Note 3: These specifications apply for $V_S = \pm 15V$ and $0^{\circ}C \leq T_A \leq +70^{\circ}C$. V_{OS} , I_B and I_{OS} are measured at $V_{CM} = 0$.

Note 4: The input bias currents are junction leakage currents which approximately double for every $10^{\circ}C$ increase in the junction temperature, T_j . Due to the limited production test time, the input bias currents measured are correlated to junction temperature. In normal operation the junction temperature rises above the ambient temperature as a result of internal power dissipation, P_D . $T_j = T_A + \theta_{JA} P_D$ where θ_{JA} is the thermal resistance from junction to ambient. Use of a heat sink is recommended if input bias current is to be kept to a minimum.

Note 5: Supply voltage rejection ratio is measured for both supply magnitudes increasing or decreasing simultaneously in accordance with common practice. From $\pm 15V$ to $\pm 5V$.

Note 6: Max. Power Dissipation is defined by the package characteristics. Operating the part near the Max. Power Dissipation may cause the part to operate outside guaranteed limits.

Application Hints

The LF351 is an op amp with an internally trimmed input offset voltage and JFET input devices (BI-FET II™). These JFETs have large reverse breakdown voltages from gate to source and drain eliminating the need for clamps across the inputs. Therefore, large differential input voltages can easily be accommodated without a large increase in input current. The maximum differential input voltage is independent of the supply voltages. However, neither of the input voltages should be allowed to exceed the negative supply as this will

cause large currents to flow which can result in a destroyed unit.

Exceeding the negative common-mode limit on either input will force the output to a high state, potentially causing a reversal of phase to the output.

Exceeding the negative common-mode limit on both inputs will force the amplifier output to a high state. In neither case does a latch occur since raising the input back within the

Application Hints (Continued)

common-mode range again puts the input stage and thus the amplifier in a normal operating mode.

Exceeding the positive common-mode limit on a single input will not change the phase of the output; however, if both inputs exceed the limit, the output of the amplifier will be forced to a high state.

The amplifier will operate with a common-mode input voltage equal to the positive supply; however, the gain bandwidth and slew rate may be decreased in this condition. When the negative common-mode voltage swings to within 3V of the negative supply, an increase in input offset voltage may occur.

The LF351 is biased by a zener reference which allows normal circuit operation on $\pm 4\text{V}$ power supplies. Supply voltages less than these may result in lower gain bandwidth and slew rate.

The LF351 will drive a $2\text{ k}\Omega$ load resistance to $\pm 10\text{V}$ over the full temperature range of 0°C to $+70^\circ\text{C}$. If the amplifier is forced to drive heavier load currents, however, an increase in input offset voltage may occur on the negative voltage swing and finally reach an active current limit on both positive and negative swings.

Precautions should be taken to ensure that the power supply for the integrated circuit never becomes reversed in polarity or that the unit is not inadvertently installed back-

wards in a socket as an unlimited current surge through the resulting forward diode within the IC could cause fusing of the internal conductors and result in a destroyed unit.

Because these amplifiers are JFET rather than MOSFET input op amps they do not require special handling.

As with most amplifiers, care should be taken with lead dress, component placement and supply decoupling in order to ensure stability. For example, resistors from the output to an input should be placed with the body close to the input to minimize "pick-up" and maximize the frequency of the feedback pole by minimizing the capacitance from the input to ground.

A feedback pole is created when the feedback around any amplifier is resistive. The parallel resistance and capacitance from the input of the device (usually the inverting input) to AC ground set the frequency of the pole. In many instances the frequency of this pole is much greater than the expected 3 dB frequency of the closed loop gain and consequently there is negligible effect on stability margin. However, if the feedback pole is less than approximately 6 times the expected 3 dB frequency a lead capacitor should be placed from the output to the input of the op amp. The value of the added capacitor should be such that the RC time constant of this capacitor and the resistance it parallels is greater than or equal to the original feedback pole time constant.

Detailed Schematic

TL/H/5648-9

Typical Applications

Supply Current Indicator/Limiter

• V_{OUT} switches high when $R_S I_S > V_D$

Hi- Z_{IN} Inverting Amplifier

Parasitic input capacitance $C1 \approx (3 \text{ pF for LF351 plus any additional layout capacitance})$ interacts with feedback elements and creates undesirable high frequency pole. To compensate, add $C2$ such that: $R2C2 \approx R1C1$.

Ultra-Low (or High) Duty Cycle Pulse Generator

- $t_{OUTPUT \text{ HIGH}} \approx R1C \ln \frac{4.8 - 2V_S}{4.8 - V_S}$
 - $t_{OUTPUT \text{ LOW}} \approx R2C \ln \frac{2V_S - 7.8}{V_S - 7.8}$
- where $V_S = V^+ + |V^-|$
- *low leakage capacitor

Long Time Integrator

- *Low leakage capacitor
- *50k pot used for less sensitive V_{OS} adjust

LF353 Wide Bandwidth Dual JFET Input Operational Amplifier

General Description

These devices are low cost, high speed, dual JFET input operational amplifiers with an internally trimmed input offset voltage (BI-FET II™ technology). They require low supply current yet maintain a large gain bandwidth product and fast slew rate. In addition, well matched high voltage JFET input devices provide very low input bias and offset currents. The LF353 is pin compatible with the standard LM1558 allowing designers to immediately upgrade the overall performance of existing LM1558 and LM358 designs.

These amplifiers may be used in applications such as high speed integrators, fast D/A converters, sample and hold circuits and many other circuits requiring low input offset voltage, low input bias current, high input impedance, high slew rate and wide bandwidth. The devices also exhibit low noise and offset voltage drift.

Features

■ Internally trimmed offset voltage	10 mV
■ Low input bias current	50pA
■ Low input noise voltage	16 nV/ $\sqrt{\text{Hz}}$
■ Low input noise current	0.01 pA/ $\sqrt{\text{Hz}}$
■ Wide gain bandwidth	4 MHz
■ High slew rate	13 V/ μs
■ Low supply current	3.6 mA
■ High input impedance	$10^{12}\Omega$
■ Low total harmonic distortion $A_V=10$, $R_L=10k$, $V_O=20V_{p-p}$, BW= 20 Hz-20 kHz	<0.02%
■ Low 1/f noise corner	50 Hz
■ Fast settling time to 0.01%	2 μs

Application Hints

These devices are op amps with an internally trimmed input offset voltage and JFET input devices (BI-FET II). These JFETs have large reverse breakdown voltages from gate to source and drain eliminating the need for clamps across the inputs. Therefore, large differential input voltages can easily be accommodated without a large increase in input current. The maximum differential input voltage is independent of the supply voltages. However, neither of the input voltages should be allowed to exceed the negative supply as this will cause large currents to flow which can result in a destroyed unit.

Exceeding the negative common-mode limit on either input will force the output to a high state, potentially causing a reversal of phase to the output. Exceeding the negative common-mode limit on both inputs will force the amplifier output to a high state. In neither case does a latch occur since raising the input back within the common-mode range again puts the input stage and thus the amplifier in a normal operating mode.

Application Hints (Continued)

Exceeding the positive common-mode limit on a single input will not change the phase of the output; however, if both inputs exceed the limit, the output of the amplifier will be forced to a high state.

The amplifiers will operate with a common-mode input voltage equal to the positive supply; however, the gain bandwidth and slew rate may be decreased in this condition. When the negative common-mode voltage swings to within 3V of the negative supply, an increase in input offset voltage may occur.

Each amplifier is individually biased by a zener reference which allows normal circuit operation on $\pm 6V$ power supplies. Supply voltages less than these may result in lower gain bandwidth and slew rate.

The amplifiers will drive a 2 k Ω load resistance to $\pm 10V$ over the full temperature range of 0°C to +70°C. If the amplifier is forced to drive heavier load currents, however, an increase in input offset voltage may occur on the negative voltage swing and finally reach an active current limit on both positive and negative swings.

Precautions should be taken to ensure that the power supply for the integrated circuit never becomes reversed in polarity or that the unit is not inadvertently installed backwards in a socket as an unlimited current surge through the result-

ing forward diode within the IC could cause fusing of the internal conductors and result in a destroyed unit.

Because these amplifiers are JFET rather than MOSFET input op amps they do not require special handling.

As with most amplifiers, care should be taken with lead dress, component placement and supply decoupling in order to ensure stability. For example, resistors from the output to an input should be placed with the body close to the input to minimize "pick-up" and maximize the frequency of the feedback pole by minimizing the capacitance from the input to ground.

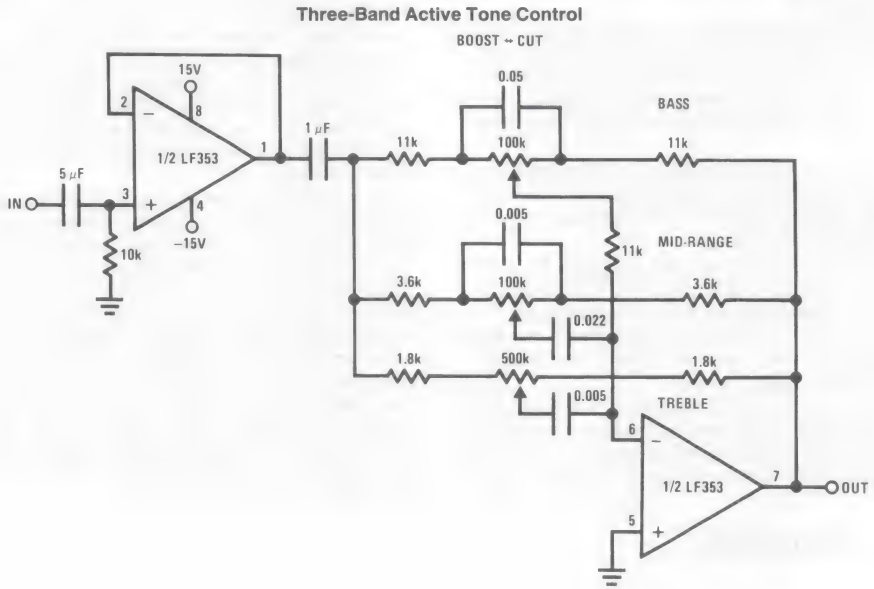

A feedback pole is created when the feedback around any amplifier is resistive. The parallel resistance and capacitance from the input of the device (usually the inverting input) to AC ground set the frequency of the pole. In many instances the frequency of this pole is much greater than the expected 3 dB frequency of the closed loop gain and consequently there is negligible effect on stability margin. However, if the feedback pole is less than approximately 6 times the expected 3 dB frequency a lead capacitor should be placed from the output to the input of the op amp. The value of the added capacitor should be such that the RC time constant of this capacitor and the resistance it parallels is greater than or equal to the original feedback pole time constant.

LF400C Fast Settling JFET Input Operational Amplifier

General Description

The LF400C is a fast settling (under 400 ns to 0.01% for a 10V output step) BI-FET operational amplifier. It also features 16 MHz bandwidth, 70 V/ μ s inverting slew rate and adjustable short circuit current limit, enabling it to drive 600 Ω loads easily.

Applications

- DAC output amplifiers
- High speed ramp generators
- Fast buffers
- Sample-and-holds
- Fast integrators
- Piezoelectric transducer signal conditioners

Typical Connection

I_S	Maximum Supply Current		$V_O = 0V$, $R_L = \infty$	9	12		9	12		mA

Note 1: Absolute Maximum Ratings indicate limits beyond which damage to the device may occur. DC and AC electrical specifications do not apply when operating the device beyond its specified operating conditions.

Note 2: All voltages are with respect to ground.

Note 3: Unless otherwise specified, the Absolute Maximum Negative Input Voltage is equal to the negative power supply voltage.

Note 4: The maximum power dissipation must be derated at elevated temperatures and is dictated by T_{JMAX} , Θ_{JA} , and the ambient temperature T_A . The maximum allowable power dissipation at any temperature is $P_D = (T_{JMAX} - T)/\Theta_{JA}$ or 500 mW, whichever is less. Θ_{JA} for the LF400H is typically $150^\circ C/W$.

Note 5: The input bias currents are junction leakage currents which approximately double for every $10^\circ C$ increase in the junction temperature T_J . Due to limited production test time, input bias currents are measured at $T_J = 25^\circ C$. In normal operation the junction temperature rises above the ambient temperature as a result of internal power dissipation P_D . Use of a heat sink is recommended when input bias current must be minimized.

Note 6: Typical values represent the most likely parametric norm.

Note 7: Guaranteed to National's AOQL (Average Outgoing Quality Level).

Note 8: Guaranteed, but not 100% production tested. These limits are not used to calculate outgoing quality levels.

Note 9: Human body model, 100 pF discharged through a 1500 Ω resistor.

Application Hints

The LF400 is a high-speed, low input bias current Bi-FET operational amplifier capable of settling to 0.01% of a 10V output swing in less than 400 ns. The rugged JFET inputs allow differential input voltages as high as 32V without a large increase in input current. However, the inputs should never be driven to voltages lower than the negative supply, as this can result in input currents large enough to damage the device. To prevent this from occurring when power is first applied, always turn the positive and negative power supplies on simultaneously, or turn the negative supply on first.

Exceeding the common-mode input range will not damage the device as long as the Absolute Maximum Ratings are not violated, but it will result in a high output voltage. Latching will not occur, however, and when the offending signal is removed the LF400 will recover quickly.

The nominal power supply voltage is $\pm 15V$, but the LF400 will operate satisfactorily from $\pm 10V$ to $\pm 16V$. The LF400 is functional down to $\pm 5V$, but performance will be degraded. (See Typical Performance curves.)

Settling Time Considerations

The settling performance of any high-speed operational amplifier is highly dependent on the external components and circuit board layout. Capacitance between the amplifier summing junction and ground affects the closed-loop transfer function and should be minimized. The compensation capacitor C_C between the output and the inverting input should be carefully chosen to counteract the effect of the

input capacitance. Since input capacitance is made up of several stray capacitances that are difficult to predict, the compensation capacitor will generally have to be determined empirically for best settling time. A good starting point is around 10 pF for $A_V = -1$.

Settling time may be verified using a circuit similar to the one in Figure 1. The LF400 is connected for inverting operation, and the output voltage is summed with the input voltage step. When the LF400's output voltage is equal to the input voltage, the voltage on the gate of Q1 will be zero. Any voltage appearing at this point will represent an error. The FET source follower output is observed on an oscilloscope, and the settling time is equal to the time required for the error signal displayed on the oscilloscope to decay to less than one-half the necessary accuracy (see oscilloscope photos of "Settling Time—Positive Output Swing" and "Settling Time—Negative Output Swing"). For a 10V input signal, settling time to 0.01% (1 mV) will occur when the displayed error is less than $\frac{1}{2}$ mV. Since settling time is strongly dependent on slew rate, settling will be faster for smaller signal swings. The LF400's inverting slew rate is faster than its non-inverting slew rate, so settling will be faster for inverting applications, as well.

It is important to note that the oscilloscope input amplifier will be overdriven during a settling time measurement, so the oscilloscope must be capable of recovering from overdrive very quickly. Very few oscilloscopes are suitable for this sort of measurement. The signal generator used for set-

Application Hints (Continued)

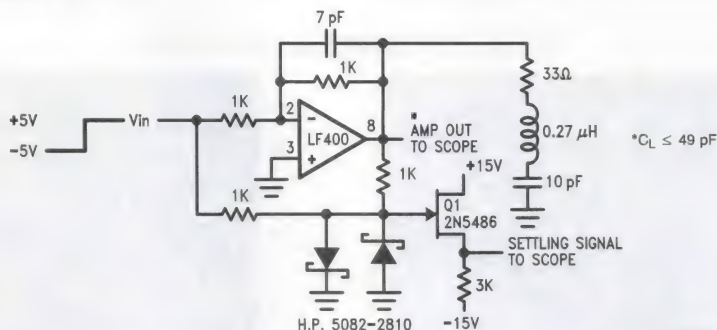

FIGURE 1. Simplified Settling Time Test Circuit (see Text)

TL/H/8393-16

ting time testing must be able to drive 50Ω with a very clean $\pm 5V$ square wave. For more information on measuring settling time, see Application Note AN-428.

Output Compensation

When operating at very low temperatures, a compensation network should be added to the LF400's output. The 100Ω/22 pF network shown on the first page of this data sheet should be used when the junction temperature might reach 25°C (roughly 0°C ambient when the LF400 is "warmed up"). In applications where the device will be operating with a junction temperature near 0°C, the output RLC network in Figure 1 should be used. This network will provide a small (about 20 ns) improvement in settling time at higher temperatures, as well.

Supply Bypassing

Power supply bypassing is extremely important for good high-speed performance. Ideally, multiple bypass capacitors as in Figure 2 should be used. A 10 μF tantalum, a 2.2 μF ceramic, and a 0.47 μF ceramic work well. All bypass capacitor leads should be very short. For best results, the ground leads of the capacitors should be separated to reduce the inductance to ground. A ground plane layout approach will give the best results. For simplicity, bypass capacitors have been omitted from some of the schematics in this data sheet, but they should always be used.

FIGURE 2. Power Supply Bypassing (see Text)

TL/H/8393-17

Output Drive and Current Limit

The LF400 can drive heavier resistive loads than most operational amplifiers. The output at pin 6 is internally current-limited when the voltage drop across the 25Ω output resistor reaches about 0.55V ($I_{OUT} = 22$ mA). When more output current is needed, pin 8 provides a means of increasing the maximum output current up to about 100 mA. A resistor may be connected from pin 8 to pin 6, paralleling the internal sense resistor and increasing the current limit threshold (Figure 3). Pins 6 and 8 may be shorted together to completely bypass the current limiting circuit. To avoid damaging the LF400, observe the power dissipation limitations mentioned in the Absolute Maximum Ratings and in Note 4.

The effective load impedance (including feedback resistance) should be kept above 500Ω for fastest settling. Load capacitance should also be minimized if good settling time is to be optimized. Large feedback resistors will make the circuit more susceptible to stray capacitance, so in high-speed applications keep the feedback resistors in the 1 kΩ to 2 kΩ range wherever practical. Avoid the use of inductive feedback resistors (some wirewounds for example) as these will degrade settling time.

TL/H/8393-18

FIGURE 3. Increasing the current limit using pin 8. Current limit is now determined by R_X in parallel with the internal 25Ω sense resistor.

V_{OS} Adjustment

Offset voltage can be nulled using a 27k resistor and a 10k potentiometer connected to pins 1 and 5 as shown in Figure 4a. Bypassing the V_{OS} adjust pins with 0.1 μF capacitors will help to avoid noise pickup. When not used for offset adjustment, pins 1 and 5 can often be left open, but to minimize the possibility of noise pickup the unused V_{OS} trim pins should be connected to ground or V^- .

Application Hints (Continued)

TL/H/8393-19

FIGURE 4a. V_{OS} Adjust Circuit

TL/H/8393-20

FIGURE 4b. Automatic Offset Adjustment Using LMC669

In very critical applications where a manual adjustment is impractical, the LMC669 Auto Zero circuit may be used to reduce the effective input offset voltage to around $5\mu\text{V}$ as in Figure 4b. The LF400 will perform better than slower amplifiers in an auto zero loop, because its fast settling capability keeps its summing node voltage more stable. Therefore, the LMC669 is able to more accurately sample the summing node voltage before making an offset correction.

Input Bias Current

The JFET input stage of the LF400 ensures low input bias current (200 pA maximum) when the die is at room temperature, but this current approximately doubles for every 10°C increase in temperature. In applications that demand the lowest possible input bias current, a heat sink should be used with the LF400. "Press on" heat sinks from manufacturers such as Thermalloy and Aavid can reduce junction temperature by roughly 10°C to 40°C .

Typical Applications

High-Speed DAC with Voltage Output

TL/H/8393-21

PRELIMINARY

LF401 Precision Fast Settling JFET Input Operational Amplifier

General Description

The LF401A is a fast settling (guaranteed under 400 ns to 0.01% for a 10V output step) BI-FET operational amplifier. The input offset voltage of the LF401A is guaranteed less than 200 μ V maximum at 25°C. The LF401 also features 16 MHz bandwidth, 70 V/ μ s inverting slew rate and adjustable short circuit current limit, enabling it to drive 600 Ω loads easily.

Applications

- DAC output amplifiers
- Fast buffers
- High speed ramp generators
- Sample-and-holds
- Fast integrators
- Piezoelectric transducer signal conditioners

Note 1: Absolute Maximum Ratings indicate limits beyond which damage to the device may occur. DC and AC electrical specifications do not apply when operating the device beyond its specified operating conditions.

Note 2: All voltages are with respect to ground.

Note 3: Unless otherwise specified, the Absolute Maximum Negative Input Voltage is equal to the negative power supply voltage.

Note 4: The maximum power dissipation must be derated at elevated temperatures and is dictated by T_{JMAX} , θ_{JA} , and the ambient temperature T_A . The maximum allowable power dissipation at any temperature is $P_D = (T_{JMAX} - T_A)/\theta_{JA}$ or 500 mW, whichever is less. θ_{JA} for the LF401D is typically $87^\circ C/W$.

Note 5: The input bias currents are junction leakage currents which approximately double for every $10^\circ C$ increase in the junction temperature T_J . Due to limited production test time, input bias currents are measured at $T_J = 25^\circ C$. In normal operation the junction temperature rises above the ambient temperature as a result of internal power dissipation P_D . Use of a heat sink is recommended when input bias current must be minimized.

Note 6: Typical values represent the most likely parametric norm.

Note 7: Guaranteed to National's AOQL (Average Outgoing Quality Level).

Note 8: Guaranteed, but not 100% production tested. These limits are not used to calculate outgoing quality levels.

Note 9: Tested and correlated to a 10 minute warm up period.

Note 10: Human body model, 100 pF discharged through a 1500Ω resistor.

Application Hints

The LF401 is a high-speed, low offset, low input bias current Bi-FET operational amplifier capable of settling to 0.01% of a 10V output swing in less than 400 ns. Input offset voltage at room temperature is less than 200 μ V for LF401A. The rugged JFET inputs allow differential input voltages as high as 32V without a large increase in input current. However, the inputs should never be driven to voltages lower than the negative supply, as this can result in input currents large enough to damage the device. To prevent this from occurring when power is first applied, always turn the positive and negative power supplies on simultaneously, or turn the negative supply on first.

Exceeding the positive common-mode input range will not damage the device as long as the Absolute Maximum ratings are not violated, but if both inputs exceed the positive common-mode range the output voltage will go high. Latching will not occur, however, and when the offending signal is removed the LF401 will recover quickly.

The nominal power supply voltage is $\pm 15\text{V}$, but the LF401 will operate satisfactorily from $\pm 10\text{V}$ to $\pm 16\text{V}$. The LF401 is functional down to $\pm 5\text{V}$, but performance will be degraded at low supply voltages. (See Typical Performance curves.)

SETTLING TIME CONSIDERATIONS

The settling performance of any fast operational amplifier is highly dependent on the external components and circuit board layout. Capacitance between the amplifier summing junction and ground affects the closed-loop transfer function and should be minimized. The compensation capacitor C_c between the output and the inverting input should be carefully chosen to counteract the effect of the input capacitance. Since input capacitance is made up of several stray

capacitances that are difficult to predict, the compensation capacitor will generally have to be determined empirically for best settling time. A good starting point is around 10 pF for $A_v = -1$.

Settling time may be verified using a circuit similar to the one in *Figure 1*. The LF401 is connected for inverting operation, and the output voltage is summed with the input voltage step. When the LF401's output voltage is equal to the input voltage, the voltage on the gate of Q1 will be zero. Any voltage appearing at this point will represent an error. The FET source follower output is observed on an oscilloscope, and the settling time is equal to the time required for the error signal displayed on the oscilloscope to decay to less than one-half the necessary accuracy (see oscilloscope photos of "Settling Time — Positive Output Swing" and "Settling Time — Negative Output Swing"). For a 10V input signal, settling time to 0.01% (1 mV) will occur when the displayed error is less than 1/2 mV. Since settling time is strongly dependent on slew rate, settling will be faster for smaller signal swings. The LF401's inverting slew rate is faster than its non-inverting slew rate, so settling will be faster for inverting applications, as well.

It is important to note that the oscilloscope input amplifier will be overdriven during a settling time measurement, so the oscilloscope must be capable of recovering from overdrive very quickly. Very few oscilloscopes are suitable for this sort of measurement. The signal generator used for settling time testing must be able to drive 50Ω with a very clean $\pm 5V$ square wave. For more information on measuring settling time, see Application Note AN-428.

OUTPUT COMPENSATION

When operating at very low temperatures, a compensation network should be connected to the LF401's "raw" output pin. The 100Ω/22 pF network shown on the first page of this data sheet should be connected to pin 14 in applications where the junction temperature might go as low as 25°C (roughly 0°C ambient when the LF401 is "warmed up"). In applications where the device will be operating with a junction temperature down to 0°C, the output RLC network in *Figure 1* should be used. This network will provide a small (about 20 ns) improvement in settling time at higher temperatures, as well.

FIGURE 1. Simplified Settling Time Test Circuit (See Text)

TL/H/8839-16

Application Hints (Continued)

TL/H/8839-17

FIGURE 2. Power Supply Bypassing (See Text)

SUPPLY BYPASSING

Power supply bypassing is extremely important for good high-speed performance. Ideally, multiple bypass capacitors as in *Figure 2* should be used. A 10 μF tantalum, a 2.2 μF ceramic, and a 0.47 μF ceramic work well. All bypass capacitor leads should be very short. For best results, the ground leads of the capacitors should be separated to reduce the inductance to ground. A ground plane layout approach will give the best results. For simplicity, bypass capacitors have been omitted from some of the schematics in this data sheet, but they should always be used.

Pins 5 through 10 are used to trim the LF401's input offset voltage during the manufacturing process. Always leave pins 7 through 10 open, as signals applied to these pins will affect the amplifier output and can permanently degrade V_{OS} . For fastest settling time to 0.01%, pins 5 and 6 should be bypassed to pin 4 with 0.1 μF capacitors; otherwise, the LF401 may take an additional 600 ns to settle. The bypass capacitors should be low-leakage film types; otherwise the offset voltage can be increased. Settling time to 0.1% will be unaffected by bypassing these pins, so they may be left unconnected in applications requiring less precision.

OUTPUT DRIVE AND CURRENT LIMIT

The LF401 can drive heavier resistive loads than most operational amplifiers. The output at pin 12 is internally current-limited when the voltage drop across the 25 Ω output resistor reaches about 0.55V ($I_{out} = 22\text{ mA}$). When more output current is needed, pin 14 provides a means of increasing the maximum output current up to about 100 mA. A resistor may be connected from pin 12 to pin 14, paralleling the

internal sense resistor and increasing the current limit threshold (*Figure 3*). Pins 12 and 14 may be shorted together to completely bypass the current limiting circuit. To avoid damaging the LF401, observe the power dissipation limitations mentioned in the Absolute Maximum Ratings and in Note 4.

TL/H/8839-18

FIGURE 3. Increasing the current limit using pin 14. Current limit is now determined by R_X in parallel with the internal 25 Ω sense resistor.

The effective load impedance (including feedback resistance) should be kept above 500 Ω for fastest settling. Load capacitance should also be minimized if good settling time is to be optimized. Large feedback resistors will make the circuit more susceptible to stray capacitance, so in high-speed applications keep the feedback resistors in the 1k to 2 k Ω range wherever practical. Avoid the use of inductive feedback resistors (some wirewounds for example) as these will degrade settling time.

V_{OS} ADJUSTMENT

Offset voltage can be nulled using a 27k resistor and a 10k potentiometer connected to pins 1 and 11 as shown in *Figure 4a*. Bypassing the V_{OS} adjust pins with 0.1 μF capacitors will help to avoid noise pickup. When not used for offset adjustment, pins 1 and 11 can often be left open, but to minimize the possibility of noise pickup the unused V_{OS} trim pins should be connected to ground or V^- .

In very critical applications where a manual adjustment is impractical, the LMC669 Auto Zero circuit may be used to reduce the effective input offset voltage to around 5 μV as in *Figure 4b*. The LF401 will perform better than slower amplifiers in an auto zero loop, because its fast settling capability keeps its summing node voltage more stable. Therefore, the LMC669 is able to more accurately sample the summing node voltage before making an offset correction.

INPUT BIAS CURRENT

The JFET input stage of the LF401 ensures low input bias current (200 pA maximum) when the die is at room temperature, but this current approximately doubles for every 10 $^{\circ}\text{C}$ increase in temperature. In applications that demand the lowest possible input bias current, a heat sink should be used with the LF401. "Slide on" heat sinks such as the AAVID 5602B can reduce the junction temperature by about 10 $^{\circ}\text{C}$.

LF411A/LF411 Low Offset, Low Drift JFET Input Operational Amplifier

General Description

These devices are low cost, high speed, JFET input operational amplifiers with very low input offset voltage and guaranteed input offset voltage drift. They require low supply current yet maintain a large gain bandwidth product and fast slew rate. In addition, well matched high voltage JFET input devices provide very low input bias and offset currents. The LF411 is pin compatible with the standard LM741 allowing designers to immediately upgrade the overall performance of existing designs.

These amplifiers may be used in applications such as high speed integrators, fast D/A converters, sample and hold circuits and many other circuits requiring low input offset voltage and drift, low input bias current, high input impedance, high slew rate and wide bandwidth.

Features

- Internally trimmed offset voltage 0.5 mV(max)
- Input offset voltage drift 10 $\mu\text{V}/^\circ\text{C}$ (max)
- Low input bias current 50 pA
- Low input noise current 0.01 pA/ $\sqrt{\text{Hz}}$
- Wide gain bandwidth 3 MHz(min)
- High slew rate 10V/ μs (min)
- Low supply current 1.8 mA
- High input impedance $10^{12}\Omega$
- Low total harmonic distortion $A_V = 10$, $R_L = 10\text{k}$, $V_O = 20\text{ Vp-p}$, $\text{BW} = 20\text{ Hz} - 20\text{ kHz}$ < 0.02%
- Low 1/f noise corner 50 Hz
- Fast settling time to 0.01% 2 μs

Typical Connection

Note 1: Unless otherwise specified the absolute maximum negative input voltage is equal to the negative power supply voltage.

Note 2: For operating at elevated temperature, these devices must be derated based on a thermal resistance of θ_{JA} .

Note 3: These devices are available in both the commercial temperature range $0^{\circ}\text{C} \leq T_A \leq 70^{\circ}\text{C}$ and the military temperature range $-55^{\circ}\text{C} \leq T_A \leq 125^{\circ}\text{C}$. The temperature range is designated by the position just before the package type in the device number. A "C" indicates the commercial temperature range and an "M" indicates the military temperature range. The military temperature range is available in "H" package only.

Note 4: Unless otherwise specified, the specifications apply over the full temperature range and for $V_S = \pm 20\text{V}$ for the LF411A and for $V_S = \pm 15\text{V}$ for the LF411. V_{OS} , I_B , and I_{OS} are measured at $V_{CM} = 0$.

Note 5: The LF411A is 100% tested to this specification. The LF411 is sample tested to insure at least 90% of the units meet this specification.

Note 6: The input bias currents are junction leakage currents which approximately double for every 10°C increase in the junction temperature, T_J . Due to limited production test time, the input bias currents measured are correlated to junction temperature. In normal operation the junction temperature rises above the ambient temperature as a result of internal power dissipation, P_D . $T_J = T_A + \theta_{JA} P_D$ where θ_{JA} is the thermal resistance from junction to ambient. Use of a heat sink is recommended if input bias current is to be kept to a minimum.

Note 7: Supply voltage rejection ratio is measured for both supply magnitudes increasing or decreasing simultaneously in accordance with common practice, from $\pm 15\text{V}$ to $\pm 5\text{V}$ for the LF411 and from $\pm 20\text{V}$ to $\pm 5\text{V}$ for the LF411A.

Note 8: Refer to RETS 411AX for LF411AMH military specifications and to RETS 411X for LF411MH military specifications.

Note 9: Max. Power Dissipation is defined by the package characteristics. Operating the part near the Max. Power Dissipation may cause the part to operate outside guaranteed limits.

Application Hints

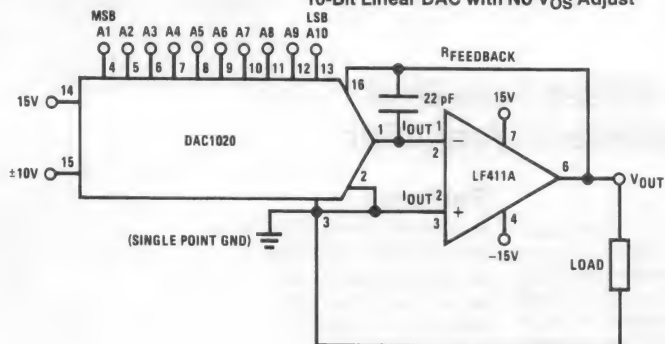

The LF411 series of internally trimmed JFET input op amps (BI-FET II™) provide very low input offset voltage and guaranteed input offset voltage drift. These JFETs have large reverse breakdown voltages from gate to source and drain eliminating the need for clamps across the inputs. Therefore, large differential input voltages can easily be accommodated without a large increase in input current. The maximum differential input voltage is independent of the supply voltages. However, neither of the input voltages should be allowed to exceed the negative supply as this will cause large currents to flow which can result in a destroyed unit.

Exceeding the negative common-mode limit on either input will force the output to a high state, potentially causing a reversal of phase to the output. Exceeding the negative common-mode limit on both inputs will force the amplifier output to a high state. In neither case does a latch occur since raising the input back within the common-mode range again puts the input stage and thus the amplifier in a normal operating mode.

Exceeding the positive common-mode limit on a single input will not change the phase of the output; however, if both inputs exceed the limit, the output of the amplifier may be forced to a high state.

Note 1: Unless otherwise specified the absolute maximum negative input voltage is equal to the negative power supply voltage.

Note 2: Any of the amplifier outputs can be shorted to ground indefinitely, however, more than one should not be simultaneously shorted as the maximum junction temperature will be exceeded.

Note 3: For operating at elevated temperature, these devices must be derated based on a thermal resistance of θ_{JA} .

Note 4: These devices are available in both the commercial temperature range $0^{\circ}\text{C} \leq T_A \leq 70^{\circ}\text{C}$ and the military temperature range $-55^{\circ}\text{C} \leq T_A \leq 125^{\circ}\text{C}$. The temperature range is designated by the position just before the package type in the device number. A "C" indicates the commercial temperature range and an "M" indicates the military temperature range. The military temperature range is available in "H" package only. In all cases the maximum operating temperature is limited by internal junction temperature T_J max.

Note 5: Unless otherwise specified, the specifications apply over the full temperature range and for $V_S = \pm 20\text{V}$ for the LF412A and for $V_S = \pm 15\text{V}$ for the LF412. V_{OS} , I_B , and I_{OS} are measured at $V_{CM} = 0$.

Note 6: The LF412A is 100% tested to this specification. The LF412 is sample tested on a per amplifier basis to insure at least 85% of the amplifiers meet this specification.

Note 7: The input bias currents are junction leakage currents which approximately double for every 10°C increase in the junction temperature, T_J . Due to limited production test time, the input bias currents measured are correlated to junction temperature. In normal operation the junction temperature rises above the ambient temperature as a result of internal power dissipation, P_D . $T_J = T_A + \theta_{JA} P_D$ where θ_{JA} is the thermal resistance from junction to ambient. Use of a heat sink is recommended if input bias current is to be kept to a minimum.

Note 8: Supply voltage rejection ratio is measured for both supply magnitudes increasing or decreasing simultaneously in accordance with common practice. $V_S = \pm 6\text{V}$ to $\pm 15\text{V}$.

Note 9: Refer to RETS412AX for LF412AMH military specifications and to RETS412X for LF412MH military specifications.

Note 10: Max. Power Dissipation is defined by the package characteristics. Operating the part near the Max. Power Dissipation may cause the part to operate outside guaranteed limits.

Application Hints

The LF412 series of JFET input dual op amps are internally trimmed (BI-FET II™) providing very low input offset voltages and guaranteed input offset voltage drift. These JFETs have large reverse breakdown voltages from gate to source and drain eliminating the need for clamps across the inputs. Therefore, large differential input voltages can easily be accommodated without a large increase in input current. The maximum differential input voltage is independent of the supply voltages. However, neither of the input voltages should be allowed to exceed the negative supply as this will cause large currents to flow which can result in a destroyed unit.

Exceeding the negative common-mode limit on either input will cause a reversal of the phase to the output and force the amplifier output to the corresponding high or low state.

Exceeding the negative common-mode limit on both inputs will force the amplifier output to a high state. In neither case does a latch occur since raising the input back within the common-mode range again puts the input stage and thus the amplifier in a normal operating mode.

Exceeding the positive common-mode limit on a single input will not change the phase of the output, however, if both inputs exceed the limit, the output of the amplifier may be forced to a high state.

The amplifiers will operate with a common-mode input voltage equal to the positive supply; however, the gain bandwidth and slew rate may be decreased in this condition. When the negative common-mode voltage swings to within 3V of the negative supply, an increase in input offset voltage may occur.

Application Hints (Continued)

Each amplifier is individually biased by a zener reference which allows normal circuit operation on $\pm 6.0\text{V}$ power supplies. Supply voltages less than these may result in lower gain bandwidth and slew rate.

The amplifiers will drive a $2\text{ k}\Omega$ load resistance to $\pm 10\text{V}$ over the full temperature range. If the amplifier is forced to drive heavier load currents, however, an increase in input offset voltage may occur on the negative voltage swing and finally reach an active current limit on both positive and negative swings.

Precautions should be taken to ensure that the power supply for the integrated circuit never becomes reversed in polarity or that the unit is not inadvertently installed backwards in a socket as an unlimited current surge through the resulting forward diode within the IC could cause fusing of the internal conductors and result in a destroyed unit.

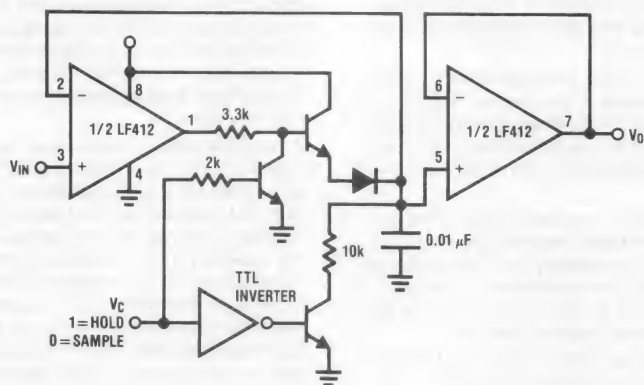

Because these amplifiers are JFET rather than MOSFET input op amps they do not require special handling.

As with most amplifiers, care should be taken with lead dress, component placement and supply decoupling in order to ensure stability. For example, resistors from the output to an input should be placed with the body close to the input to minimize "pick-up" and maximize the frequency of the feedback pole by minimizing the capacitance from the input to ground.

A feedback pole is created when the feedback around any amplifier is resistive. The parallel resistance and capacitance from the input of the device (usually the inverting input) to AC ground set the frequency of the pole. In many instances the frequency of this pole is much greater than the expected 3 dB frequency of the closed loop gain and consequently there is negligible effect on stability margin. However, if the feedback pole is less than approximately 6 times the expected 3 dB frequency a lead capacitor should be placed from the output to the input of the op amp. The value of the added capacitor should be such that the RC time constant of this capacitor and the resistance it parallels is greater than or equal to the original feedback pole time constant.

Typical Application

Single Supply Sample and Hold

LF441A/LF441 Low Power JFET Input Operational Amplifier

General Description

The LF441A/441 low power operational amplifier provides many of the same AC characteristics as the industry standard LM741 while greatly improving the DC characteristics of the LM741. The amplifier has the same bandwidth, slew rate, and gain (10 k Ω load) as the LM741 and only draws one tenth the supply current of the LM741. In addition, the well matched high voltage JFET input devices of the LF441A/441 reduce the input bias and offset currents by a factor of 10,000 over the LM741. A combination of careful layout design and internal trimming guarantees very low input offset voltage and voltage drift. The LF441A/441 also has a very low equivalent input noise voltage for a low power amplifier.

The LF441A/441 is pin compatible with the LM741, allowing an immediate 10 times reduction in power drain in many applications. The LF441A/441 should be used where low

power dissipation and good electrical characteristics are the major considerations.

Features

■ 1/10 supply current of a LM741	200 μ A (max)
■ Low input bias current	50 pA (max)
■ Low input offset voltage	0.5 mV (max)
■ Low input offset voltage drift	10 μ V/ $^{\circ}$ C (max)
■ High gain bandwidth	1 MHz
■ High slew rate	1 V/ μ s
■ Low noise voltage for low power	35 nV/ $\sqrt{\text{Hz}}$
■ Low input noise current	0.01 pA/ $\sqrt{\text{Hz}}$
■ High input impedance	$10^{12}\Omega$
■ High gain $V_O = \pm 10\text{V}$, $R_L = 10\text{k}$	50k (min)

Application Hints

This device is a low power op amp with an internally trimmed input offset voltage and JFET input devices (BI-FET II). These JFETs have large reverse breakdown voltages from gate to source and drain, eliminating the need for clamps across the inputs. Therefore, large differential input voltages can easily be accommodated without a large increase in input current. The maximum differential input voltage is independent of the supply voltages. However, neither of the input voltages should be allowed to exceed the negative supply as this will cause large currents to flow which can result in a destroyed unit.

Exceeding the negative common-mode limit on either input will force the output to a high state, potentially causing a reversal of phase to the output. Exceeding the negative common-mode limit on both inputs will force the amplifier output to a high state. In neither case does a latch occur since raising the input back within the common-mode range again puts the input stage and thus the amplifier in a normal operating mode.

Exceeding the positive common-mode limit on a single input will not change the phase of the output; however, if both inputs exceed the limit, the output of the amplifier will be forced to a high state.

The amplifier will operate with a common-mode input voltage equal to the positive supply; however, the gain bandwidth and slew rate may be decreased in this condition. When the negative common-mode voltage swings to within 3V of the negative supply, an increase in input offset voltage may occur.

The amplifier is biased to allow normal circuit operation with power supplies of $\pm 3\text{V}$. Supply voltages less than these may degrade the common-mode rejection and restrict the output voltage swing.

The amplifier will drive a $10\text{ k}\Omega$ load resistance to $\pm 10\text{V}$ over the full temperature range.

Precautions should be taken to ensure that the power supply for the integrated circuit never becomes reversed in polarity or that the unit is not inadvertently installed backwards in a socket, as an unlimited current surge through the resulting forward diode within the IC could cause fusing of the internal conductors and result in a destroyed unit.

Because this amplifier is a JFET rather than MOSFET input op amp it does not require special handling.

As with most amplifiers, care should be taken with lead dress, component placement and supply decoupling in order to ensure stability. For example, resistors from the output to an input should be placed with the body close to the input to minimize "pick-up" and maximize the frequency of the feedback pole by minimizing the capacitance from the input to ground.

A feedback pole is created when the feedback around any amplifier is resistive. The parallel resistance and capacitance from the input of the device (usually the inverting input to AC ground) set the frequency of this pole. In many instances the frequency of this pole is much greater than the expected 3 dB frequency, of the closed loop gain and consequently there is negligible effect on stability margin. However, if the feedback pole is less than approximately 6 times the expected 3 dB frequency, a lead capacitor should be placed from the output to the input of the op amp. The value of the added capacitor should be such that the RC time constant of this capacitor and the resistance it parallels is greater than or equal to the original feedback pole time constant.

Note 1: Unless otherwise specified the absolute maximum negative input voltage is equal to the negative power supply voltage.

Note 2: Any of the amplifier outputs can be shorted to ground indefinitely, however, more than one should not be simultaneously shorted as the maximum junction temperature will be exceeded.

Note 3: The value given is in 400 linear feet/min air flow.

Note 4: The value given is in static air.

Note 5: These devices are available in both the commercial temperature range $0^{\circ}\text{C} \leq T_A \leq 70^{\circ}\text{C}$ and the military temperature range $-55^{\circ}\text{C} \leq T_A \leq 125^{\circ}\text{C}$. The temperature range is designated by the position just before the package type in the device number. A "C" indicates the commercial temperature range and an "M" indicates the military temperature range. The military temperature range is available in "H" package only.

Note 6: Unless otherwise specified, the specifications apply over the full temperature range and for $V_S = \pm 20\text{V}$ for the LF442A and for $V_S = \pm 15\text{V}$ for the LF442. V_{OS} , I_B , and I_{OS} are measured at $V_{CM} = 0$.

Note 7: The input bias currents are junction leakage currents which approximately double for every 10°C increase in the junction temperature, T_j . Due to limited production test time, the input bias currents measured are correlated to junction temperature. In normal operation the junction temperature rises above the ambient temperature as a result of internal power dissipation, P_D . $T_j = T_A + \theta_{JA}P_D$ where θ_{JA} is the thermal resistance from junction to ambient. Use of a heat sink is recommended if input bias current is to be kept to a minimum.

Note 8: Supply voltage rejection ratio is measured for both supply magnitudes increasing or decreasing simultaneously in accordance with common practice from $\pm 15\text{V}$ to $\pm 5\text{V}$ for the LF442 and $\pm 20\text{V}$ to $\pm 5\text{V}$ for the LF442A.

Note 9: Refer to RETS442AX for LF442AMH military specifications and to RETS442X for LF442MH military specifications.

Application Hints

This device is a dual low power op amp with internally trimmed input offset voltages and JFET input devices (BI-FET II). These JFETs have large reverse breakdown voltages from gate to source and drain eliminating the need for clamps across the inputs. Therefore, large differential input voltages can easily be accommodated without a large increase in input current. The maximum differential input voltage is independent of the supply voltages. However, neither of the input voltages should be allowed to exceed the negative supply as this will cause large currents to flow which can result in a destroyed unit.

Exceeding the negative common-mode limit on either input will force the output to a high state, potentially causing a reversal of phase to the output. Exceeding the negative common-mode limit on both inputs will force the amplifier output to a high state. In neither case does a latch occur since raising the input back within the common-mode range again puts the input stage and thus the amplifier in a normal operating mode.

Exceeding the positive common-mode limit on a single input will not change the phase of the output; however, if both inputs exceed the limit, the output of the amplifier will be forced to a high state.

The amplifiers will operate with a common-mode input voltage equal to the positive supply; however, the gain bandwidth and slew rate may be decreased in this condition. When the negative common-mode voltage swings to within 3V of the negative supply, an increase in input offset voltage may occur.

Each amplifier is individually biased to allow normal circuit operation with power supplies of $\pm 3.0\text{V}$. Supply voltages less than these may degrade the common-mode rejection and restrict the output voltage swing.

The amplifiers will drive a $10\text{ k}\Omega$ load resistance to $\pm 10\text{V}$ over the full temperature range.

Precautions should be taken to ensure that the power supply for the integrated circuit never becomes reversed in polarity or that the unit is not inadvertently installed backwards in a socket as an unlimited current surge through the resulting forward diode within the IC could cause fusing of the internal conductors and result in a destroyed unit.

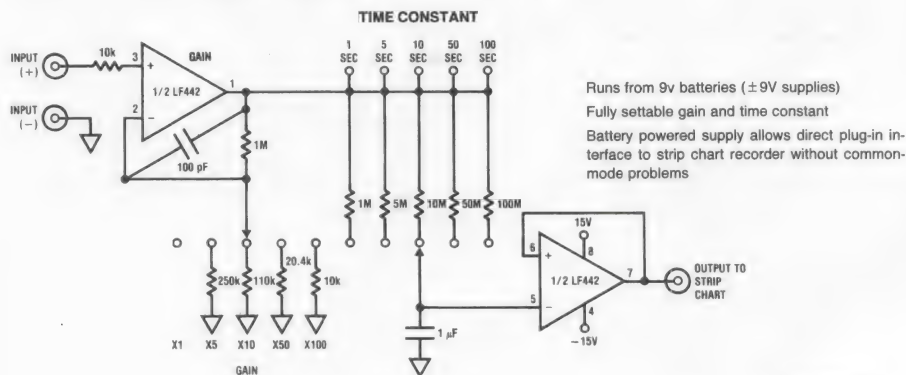

Because these amplifiers are JFET rather than MOSFET input op amps they do not require special handling.

As with most amplifiers, care should be taken with lead dress, component placement and supply decoupling in order to ensure stability. For example, resistors from the output to an input should be placed with the body close to the input to minimize "pick-up" and maximize the frequency of the feedback pole by minimizing the capacitance from the input to ground.

A feedback pole is created when the feedback around any amplifier is resistive. The parallel resistance and capacitance from the input of the device (usually the inverting input) to AC ground set the frequency of the pole. In many instances the frequency of this pole is much greater than the expected 3 dB frequency of the closed loop gain and consequently there is negligible effect on stability margin. However, if the feedback pole is less than approximately 6 times the expected 3 dB frequency a lead capacitor should be placed from the output to the input of the op amp. The value of the added capacitor should be such that the RC time constant of this capacitor and the resistance it parallels is greater than or equal to the original feedback pole time constant.

LF444A/LF444

LF444A/LF444 Quad Low Power JFET Input Operational Amplifier

General Description

The LF444 quad low power operational amplifier provides many of the same AC characteristics as the industry standard LM148 while greatly improving the DC characteristics of the LM148. The amplifier has the same bandwidth, slew rate, and gain (10 k Ω load) as the LM148 and only draws one fourth the supply current of the LM148. In addition the well matched high voltage JFET input devices of the LF444 reduce the input bias and offset currents by a factor of 10,000 over the LM148. The LF444 also has a very low equivalent input noise voltage for a low power amplifier.

The LF444 is pin compatible with the LM148 allowing an immediate 4 times reduction in power drain in many applications. The LF444 should be used wherever low power dissipation and good electrical characteristics are the major considerations.

Features

- $\frac{1}{4}$ supply current of a LM148 200 μ A/Amplifier (max)
- Low input bias current 50 pA (max)
- High gain bandwidth 1 MHz
- High slew rate 1 V/ μ s
- Low noise voltage for low power 35 nV/ $\sqrt{\text{Hz}}$
- Low input noise current 0.01 pA/ $\sqrt{\text{Hz}}$
- High input impedance $10^{12}\Omega$
- High gain $V_O = \pm 10\text{V}$, $R_L = 10\text{k}$ 50k (min)

i_n	Equivalent Input Noise Current	$T_A = 25^\circ C, f = 1\text{ kHz}$		0.01			0.01		pA/ \sqrt{Hz}

Note 1: Unless otherwise specified the absolute maximum negative input voltage is equal to the negative power supply voltage.

Note 2: Any of the amplifier outputs can be shorted to ground indefinitely, however, more than one should not be simultaneously shorted as the maximum junction temperature will be exceeded.

Note 3: For operating at elevated temperature, these devices must be derated based on a thermal resistance of θ_{JA} .

Note 4: The LF444A is available in both the commercial temperature range $0^\circ C \leq T_A \leq 70^\circ C$ and the military temperature range $-55^\circ C \leq T_A \leq 125^\circ C$. The LF444 is available in the commercial temperature range only. The temperature range is designated by the position just before the package type in the device number. A "C" indicates the commercial temperature range and an "M" indicates the military temperature range. The military temperature range is available in "D" package only.

Note 5: Unless otherwise specified the specifications apply over the full temperature range and for $V_S = \pm 20V$ for the LF444A and for $V_S = \pm 15V$ for the LF444. V_{OS} , I_B , and I_{OS} are measured at $V_{CM} = 0$.

Note 6: The input bias currents are junction leakage currents which approximately double for every $10^\circ C$ increase in the junction temperature, T_J . Due to limited production test time, the input bias currents measured are correlated to junction temperature. In normal operation the junction temperature rises above the ambient temperature as a result of internal power dissipation, P_D . $T_J = T_A + \theta_{JA}P_D$ where θ_{JA} is the thermal resistance from junction to ambient. Use of a heat sink is recommended if input bias current is to be kept to a minimum.

Note 7: Supply voltage rejection ratio is measured for both supply magnitudes increasing or decreasing simultaneously in accordance with common practice from $\pm 15V$ to $\pm 5V$ for the LF444 and from $\pm 20V$ to $\pm 5V$ for the LF444A.

Note 8: Refer to RETS444AX for LF444AMD military specifications.

Note 9: Max. Power Dissipation is defined by the package characteristics. Operating the part near the Max. Power Dissipation may cause the part to operate outside guaranteed limits.

Application Hints

This device is a quad low power op amp with JFET input devices (BI-FET™). These JFETs have large reverse breakdown voltages from gate to source and drain eliminating the need for clamps across the inputs. Therefore, large differential input voltages can easily be accommodated without a large increase in input current. The maximum differential input voltage is independent of the supply voltages. However, neither of the input voltages should be allowed to exceed the negative supply as this will cause large currents to flow which can result in a destroyed unit.

Exceeding the negative common-mode limit on either input will force the output to a high state, potentially causing a reversal of phase to the output. Exceeding the negative common-mode limit on both inputs will force the amplifier output to a high state. In neither case does a latch occur since raising the input back within the common-mode range again puts the input stage and thus the amplifier in a normal operating mode.

Exceeding the positive common-mode limit on a single input will not change the phase of the output; however, if both inputs exceed the limit, the output of the amplifier will be forced to a high state.

The amplifiers will operate with a common-mode input voltage equal to the positive supply; however, the gain bandwidth and slew rate may be decreased in this condition. When the negative common-mode voltage swings to within 3V of the negative supply, an increase in input offset voltage may occur.

Each amplifier is individually biased to allow normal circuit operation with power supplies of $\pm 3.0\text{V}$. Supply voltages less than these may degrade the common-mode rejection and restrict the output voltage swing.

The amplifiers will drive a $10\text{ k}\Omega$ load resistance to $\pm 10\text{V}$ over the full temperature range. If the amplifier is forced to drive heavier load currents, however, an increase in input offset voltage may occur on the negative voltage swing and finally reach an active current limit on both positive and negative swings.

Precautions should be taken to ensure that the power supply for the integrated circuit never becomes reversed in polarity or that the unit is not inadvertently installed backwards in a socket as an unlimited current surge through the resulting forward diode within the IC could cause fusing of the internal conductors and result in a destroyed unit.

Because these amplifiers are JFET rather than MOSFET input op amps they do not require special handling.

As with most amplifiers, care should be taken with lead dress, component placement and supply decoupling in order to ensure stability. For example, resistors from the output to an input should be placed with the body close to the input to minimize "pick-up" and maximize the frequency of the feedback pole by minimizing the capacitance from the input to ground.

A feedback pole is created when the feedback around any amplifier is resistive. The parallel resistance and capacitance from the input of the device (usually the inverting input) to AC ground set the frequency of the pole. In many instances the frequency of this pole is much greater than the expected 3 dB frequency of the closed loop gain and consequently there is negligible effect on stability margin. However, if the feedback pole is less than approximately 6 times the expected 3 dB frequency a lead capacitor should be placed from the output to the input of the op amp. The value of the added capacitor should be such that the RC time constant of this capacitor and the resistance it parallels is greater than or equal to the original feedback pole time constant.

Typical Application

pH Probe Amplifier/Temperature Compensator

**Polystyrene

*Film resistor type RN60C

To calibrate, insert probe in pH = 7 solution. Set "temp" dial to solution temperature, then, set "calibrate" dial so output reads 7V.

ADVANCED INFORMATION

LF455/LF456/LF457 Series Monolithic JFET Input Operational Amplifiers

General Description

The LF455/LF456/LF457 family of high-performance Bi-FET™ operational amplifiers features extremely low offset voltage, high gain, low noise, wide bandwidth, and high slew rate. External offset adjustments will not degrade common-mode rejection or offset drift. A non-current-limited output is provided, and may be used alone or with the normal output to increase the current limit to more than 100 mA. Either output is capable of driving large capacitive loads of up to 10,000 pF.

Applications

- DAC output amplifiers
- Precision Buffers
- Fast Integrators
- Precision, high speed instrumentation
- Precision sample and holds

Features

- Low input offset voltage 250 μ V
- Low offset voltage drift 3 μ V/°C
- Low input bias current 50 pA
- Low input offset current 10 pA
- High common-mode rejection ratio 100 dB
- High DC voltage gain 106 dB
- High slew rate: LF455 5V/ μ s
- LF456 12V/ μ s
- LF457 50V/ μ s
- Wide bandwidth: LF455 3 MHz
- LF456 5 MHz
- LF457 20 MHz
- Low input noise voltage: LF455 12nV/ $\sqrt{\text{Hz}}$ @ 1kHz
- LF456, LF457 10nV/ $\sqrt{\text{Hz}}$ @ 1kHz
- Large capacitive load capability 10,000 pF
- Fast settling to 0.01% 1.5 μ s

Typical Connection

TL/H/9225-1

$\frac{R_F}{R_I}$ must be greater than 4 for the LF457.

LF455 and LF456 are unity gain stable.

Application Hints

GENERAL CHARACTERISTICS

The LF13741 makes the job of converting from a bipolar to an FET input op amp easy. As a systems designer you are probably very familiar with the operating characteristics of a 741 op amp. In fact, many of you have used 741s with FET input followers—that's just what the LF13741 is, but it's all on a single die.

When you need a low cost, reliable, well known op amp with low input currents and moderate speed, use an LF13741.

DIFFERENTIAL INPUTS

You don't have to use clamps across the inputs for differential input voltages of less than 40V. The input JFETs of the LF13741, in addition to being well matched, have large reverse breakdown voltages from gate to source and drain.

POSITIVE INPUT COMMON-MODE VOLTAGE LIMIT

With the LF13741 (unlike the normal 741) you can take both inputs above the positive supply voltage by more than 0.1V before the amplifier ceases to function. This feature enables you to use the LF13741 to monitor and/or limit the current from the same supply used to power it (see typical applications).

If you exceed the positive common-mode voltage limit on only one input, the output phase will remain correct. When you exceed the limit on both inputs, the output phase is unpredictable.

NEGATIVE INPUT COMMON-MODE VOLTAGE LIMIT

There are two negative input voltage ranges of interest:

1. The range between the negative common-mode voltage limit and the negative supply voltage.
2. Voltages which are more negative than the negative supply voltage.

If you take only one of the inputs of the LF13741 into the first range, the output phase will remain correct. When you take both inputs into this range the output will go toward the positive supply voltage.

If you force either or both of the inputs into the second range, an internal diode will be turned "ON." Unless you externally limit the diode current to about 1 mA, the device will be destroyed. In either case, limited or unlimited input current, you cannot predict the output.

HANDLING

You do not have to take any special precautions in handling the LF13741. It has JFET, as opposed to fragile MOSFET, inputs.

APPLYING POWER

You should never: reverse the power supplies to the LF13741; plug a part in backwards in a powered socket or board; make the negative supply voltage more positive than an input voltage.

Any one of these supply conditions will forward bias an internal diode. If you have not externally limited the resulting current, the device will be destroyed.

LAYOUT

To ensure stability of response you should take care with lead dress, component placement and power supply decoupling. For example, the body of feedback resistors (from output to input pins) should be placed close to the inverting input pin. Noise "pickup" and capacitance to ground from the input pin will be minimized—effects which are usually desirable.

Because of the very low input bias currents of the LF13741, special care should be taken in printed circuit board layouts to prevent unnecessary leakage from the input nodes, (see Typical Applications).

Application Hints (Continued)

FEEDBACK POLE

You create a feedback pole when you place resistive feedback around an amplifier. The parallel resistance and capacitance from the input of the device (usually the inverting input) to AC ground set the frequency of the pole. In many instances the frequency of this pole is much greater than the expected 3 dB frequency of the closed loop gain and there is negligible effect on stability margin. However, if the feedback pole is less than approximately six times the expected 3 dB frequency (a distinct possibility when using FET op amps), you should place a lead capacitor from the output to the input of the op amp. The value of the added capacitor should be such that the RC time constant of this capacitor and the resistance it parallels is greater than or equal to the original feedback pole time constant (Figure 1).

TL/H/9296-9

Parasitic input capacitance $C1 \approx (3 \text{ pF for LF13741 plus any additional layout capacitance})$ interacts with feedback elements and creates undesirable high frequency pole. To compensate, add C2 such that: $R2C2 \approx R1C1$.

PRELIMINARY

LH0003/LH0003C Wide Bandwidth Operational Amplifier

General Description

The LH0003/LH0003C is a general purpose operational amplifier which features: slewing rate up to 70 V/ μ s, a gain bandwidth of up to 30 MHz, and high output currents.

The LH0003 is specified for operation over the -55°C to $+125^{\circ}\text{C}$ military temperature range. The LH0003C is specified for operation over the 0°C to $+85^{\circ}\text{C}$ temperature range.

Features

- Very low offset voltage Typically 0.4 mV
- Large output swing $> \pm 10\text{V}$ into 100Ω load
- High CMRR Typically $> 90\text{ dB}$
- Good large signal frequency response 50 kHz to 400 kHz depending on compensation

LH0004/LH0004C High Voltage Operational Amplifier

General Description

The LH0004/LH0004C is a general purpose operational amplifier designed to operate from supply voltages up to $\pm 40V$. The device dissipates extremely low quiescent power, typically 8 mW at $25^{\circ}C$ and $V_S = \pm 40V$.

The LH0004's high gain and wide range of operating voltages make it ideal for applications requiring large output swing and low power dissipation.

The LH0004 is specified for operation over the $-55^{\circ}C$ to $+125^{\circ}C$ military temperature range. The LH0004C is specified for operation over the $0^{\circ}C$ to $+85^{\circ}C$ temperature range.

Features

- Capable of operation over the range of $\pm 5V$ to $\pm 40V$
- Large output voltage typically $\pm 35V$ for the LH0004 and $\pm 33V$ for the LH0004C into a 2 k Ω load with $\pm 40V$ supplies

- Low input offset current typically 20 nA for the LH0004 and 45 nA for the LH0004C
- Low input offset voltage typically 0.3 mV
- Frequency compensation with 2 small capacitors
- Low power consumption 8 mW at $\pm 40V$

Applications

- Precision high voltage power supply
- Resolver excitation
- Wideband high voltage amplifier
- Transducer power supply

Schematic and Connection Diagrams

TL/H/5559-1

TL/H/5559-2

Note: Pin 7 must be grounded or connected to a voltage at least 5V more negative than the positive supply (Pin 9). Pin 7 may be connected to the negative supply; however, the standby current will be increased. A resistor may be inserted in series with Pin 7 to Pin 9. The value of the resistor should be a maximum of 100 k Ω per volt of potential between Pin 3 and Pin 9.

LH0020/LH0020C High Gain Operational Amplifier

General Description

The LH0020/LH0020C is a general purpose operational amplifier designed to source and sink 50 mA output currents. In addition to its high output capability, the LH0020/LH0020C exhibits excellent open loop gain, typically in excess of 100 dB. The parameters of the LH0020 are guaranteed over the temperature range of -55°C to $+125^{\circ}\text{C}$ and $\pm 5\text{V} \leq V_S \leq \pm 22\text{V}$, while those of the LH0020C are guaranteed over the temperature range of 0°C to $+85^{\circ}\text{C}$ and $\pm 5\text{V} \leq V_S \leq \pm 18\text{V}$.

Output current capability, excellent input characteristics, and large open loop gain make the LH0020/LH0020C suitable for application in a wide variety of applications from precision DC power supplies to precision medium power comparator.

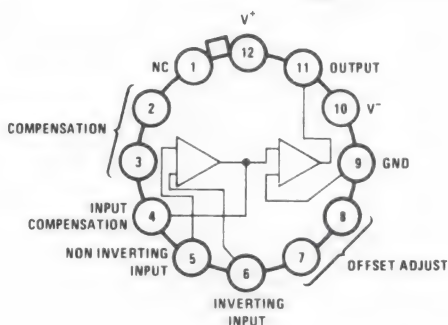

Features

- Low offset voltage typically 1.0 mV at 25°C over the entire common-mode voltage range
- Low offset current typically 10 nA at 25°C for the LH0020 and 30 nA for the LH0020C
- Offset voltage is adjustable to zero with a single potentiometer
- $\pm 14\text{V}$, 50 mA output capability

Note 1: For supply voltages less than $\pm 15\text{V}$, the absolute maximum input voltage is equal to the supply voltage.

Note 2: These specifications apply for $\pm 5\text{V} \leq V_S \leq \pm 22\text{V}$ for the LH0020, $\pm 5\text{V} \leq V_S \leq \pm 18\text{V}$ for the LH0020C, pin 9 grounded, and a 5000 pF capacitor between pins 2 and 3, unless otherwise specified.

Note 3: Refer to RETS0020G for LH0020G military specifications.

Typical Applications

LH0021-200 1.0 Amp Power Operational Amplifier

General Description

The LH0021-200 is a general purpose operational amplifier capable of delivering large output currents not usually associated with conventional IC op amps. The LH0021 will provide output currents in excess of one ampere at voltage levels of $\pm 12V$. In addition, both the inputs and outputs are protected against overload. The devices are compensated with a single external capacitor and are free of any unusual oscillation or latchup problems.

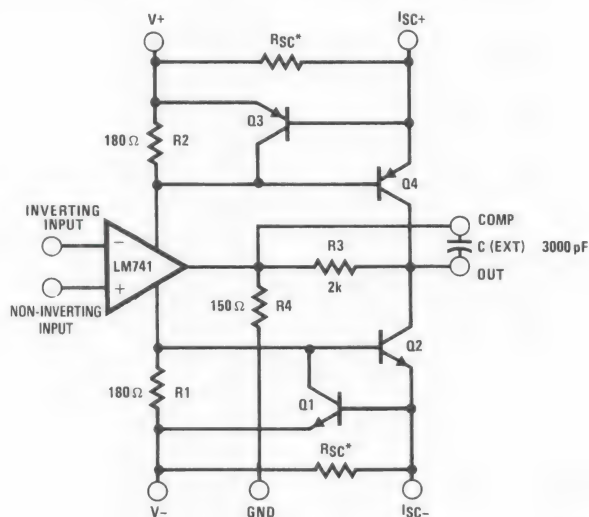

The excellent input characteristics and high output capability of the LH0021-200 make it an ideal choice for power applications such as DC servos, capstan drivers, deflection yoke drivers, and programmable power supplies.

The LH0021-200 is supplied in an 8-pin TO-3 package rated at 20W with a suitable heatsink. Also, the LH0021-200 is guaranteed over the temperature range of $-55^{\circ}C$ to $+200^{\circ}C$.

Features

- $200^{\circ}C$ Operation
- Output current 1.0A
- Output voltage swing $\pm 12V$ into 10Ω
- Wide full power bandwidth 15 kHz
- Low standby power 100 mW at $\pm 15V$
- Low input offset voltage and current 1 mV and 20 nA
- High slew rate $3.0 V/\mu s$
- High open loop gain 100 dB
- Expected life in operation 160 Hours

AC Electrical Characteristics for LH0021-200 ($T_A = 25^\circ\text{C}$, $V_S = \pm 15\text{V}$, $C_C = 3000\text{ pF}$)

Symbol	Parameter	Conditions	Limits			Units
			Min	Typ	Max	
	Slew Rate	$A_V = +1$, $R_L = 100\Omega$		3.0		V/ μ s
	Power Bandwidth	$R_L = 100\Omega$		20		kHz

Note 1: Rating applies for supply voltages greater than $\pm 15\text{V}$. For supplies less than $\pm 15\text{V}$, rating is equal to supply voltages.

Note 2: Rating applies for LH0021K-200 with $R_{SC} = 0\Omega$.

Note 3: Rating applies as long as package rating is not exceeded.

Note 4: Test conditions are $V_S = \pm 15\text{V}$, $R_S = 100\Omega$, $C_C = 3000\text{ pF}$ and apply for $-55^\circ\text{C} \leq T_A \leq 200^\circ\text{C}$ unless otherwise specified.

Note 5: For further information, see the LH0021/LH0021C Datasheet.

Note 6: In order to limit maximum junction temperature to $+225^\circ\text{C}$ it may be necessary to operate with $V_S < \pm 15\text{V}$ when T_A or T_C exceeds specific values depending on the P_D within the device package. Total P_D is the sum of quiescent and load-related dissipation.

LH0022/LH0022C High Performance FET Op Amp **LH0042/LH0042C Low Cost FET Op Amp** **LH0052/LH0052C Precision FET Op Amp**

General Description

The LH0022/LH0042/LH0052 are a family of FET input operational amplifiers with very closely matched input characteristics, very high input impedance, and ultra-low input currents with no compromise in noise, common mode rejection ratio, open loop gain, or slew rate. The internally laser nulled LH0052 offers 500 μV maximum offset and 2 $\mu\text{V}/^\circ\text{C}$ offset drift. Input offset current is less than 500 femtoamps at room temperature and 500 pA maximum at 125°C. The LH0022 and LH0042 are not internally nulled but offer comparable matching characteristics. All devices in the family are internally compensated and are free of latch-up and unusual oscillation problems. The devices may be offset nulled with a single 10k trimpot with negligible effect in CMRR.

The LH0022, LH0042 and LH0052 are specified for operation over the -55°C to $+125^\circ\text{C}$ military temperature range. The LH0022C, LH0042C and LH0052C are specified for operation over the -25°C to $+85^\circ\text{C}$ temperature range.

The LH0022/LH0042/LH0052 family of IC op amps are intended to fulfill a wide variety of applications for process control, medical instrumentation, and other systems requiring very low input currents and tightly matched input offsets. The LH0052 is particularly suited for long term high

accuracy integrators and high accuracy sample and hold buffer amplifiers. The LH0022 and LH0042 provide low cost high performance for such applications as electrometer and photocell amplification, pico-ammeters, and high input impedance buffers.

Special electrical parameter selection is available on special request.

For additional application information and information on other National operational amplifiers, see *Available Linear Applications Literature*.

Features

- Low input offset current—500 femtoamps max (LH0052)
- Low input offset drift—2 $\mu\text{V}/^\circ\text{C}$ typ (LH0052)
- Low input offset voltage—100 μV typ
- High open loop gain—100 dB typ
- Excellent slew rate—3.0 $\text{V}/\mu\text{s}$ typ
- Internal 6 dB/octave frequency compensation
- Pin compatible with standard IC op amps (TO-5 package)

Note 1: For supply voltages less than ±15V, the absolute maximum input voltage is equal to the supply voltage.

Note 2: Rating applies for minimum source resistance of 10 kΩ, for source resistances less than 10 kΩ, maximum differential input voltage is ±5V.

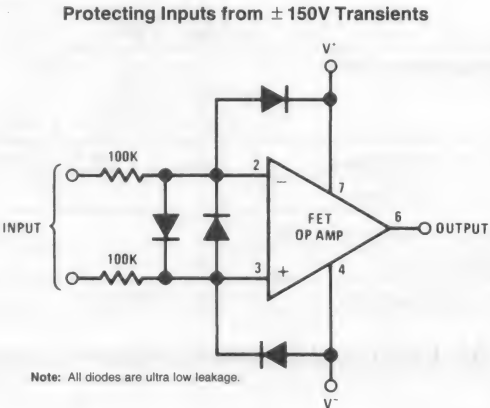

Note 3: Unless otherwise specified, these specifications apply for ±5V ≤ V_S ≤ +20V and -55°C ≤ T_A ≤ +125°C for the LH0022/42/52 and -25°C ≤ T_A ≤ +85°C for the LH0022C/42C/52C. Typical values are given for T_A = 25°C.

Note 4: Input currents are a strong function of temperature. Due to high speed testing they are specified at a junction temperature T_J = 25°C. Self heating will cause an increase in current in manual tests. 25°C spec is guaranteed by testing at 125°C.

The circuit diagram shows a precision differential amplifier. It features two input terminals labeled "INPUTS" with positive (+) and negative (-) polarity markings. The inputs are connected through shielded cables to the non-inverting inputs (pins 3 and 5) of two LM0052 operational amplifiers. The LM0052 at pin 3 has its inverting input (pin 2) connected to a voltage divider consisting of two 1MΩ resistors (0.1% tolerance) and a potentiometer labeled "GAIN ADJUST". The LM0052 at pin 5 has its inverting input (pin 4) connected to a similar network with two 1MΩ resistors and a potentiometer labeled "ZERO ADJ". Both op-amp outputs (pins 6 and 7) are connected to the inputs of an LM725 precision centration amplifier. The LM725's non-inverting input (pin 3) is also connected to ground via a 450KΩ resistor (1% tolerance). The LM725's output (pin 6) provides the final "OUTPUT". Power supplies include +15V and -15V rails connected to the LM110 and LM0052 op-amps, and a V⁻ rail connected to the LM725. Various resistors are specified with their values and tolerances: 1MΩ 0.1%, 40KΩ 0.05%, 10KΩ 0.05%, 500KΩ 0.05%, 450KΩ 1%, 100KΩ, and 10KΩ.

The diagram shows a Precision Integrator circuit. At the top, an AH0133 integrated circuit is enclosed in a dashed box. It has four pins: 13 (TTL INTEGRATE/RESET CONTROL), 9, 10 (ground), and 14. Inside the box, there are two AND gates and two inverters. The control signal at pin 13 is connected to the inputs of both AND gates. The output of the top AND gate is connected to pin 8, and the output of the bottom AND gate is connected to pin 7. Pin 10 is connected to ground. Pin 14 is connected to the non-inverting input (pin 6) of the LH0052 operational amplifier. The AH0133 also contains a resistor R4 (10K) connected between pins 7 and 1. Below the AH0133, the LH0052 operational amplifier is shown. Its non-inverting input (pin 6) is connected to the output of the AH0133 (pin 14). Its inverting input (pin 2) is connected to the input signal V₁ through resistor R1 (10⁹Ω), and to the output through resistor R2. A feedback capacitor C1 (1μF) is connected between the output (pin 6) and the inverting input (pin 2). The non-inverting input (pin 3) is connected to the initial condition V₂ through resistor R3. The output of the op-amp is labeled OUTPUT. The transfer function is given as $V_{OUT} = \frac{1}{C_1 R_1} \int -v_1 dt + V_2$.

LH0024/LH0024C High Slew Rate Operational Amplifier

General Description

The LH0024/LH0024C is a very wide bandwidth, high slew rate operational amplifier intended to fulfill a wide variety of high speed applications such as buffers to A to D and D to A converters and high speed comparators. The device exhibits useful gain in excess of 50 MHz making it possible to use in video applications requiring higher gain accuracy than is usually associated with such amplifiers.

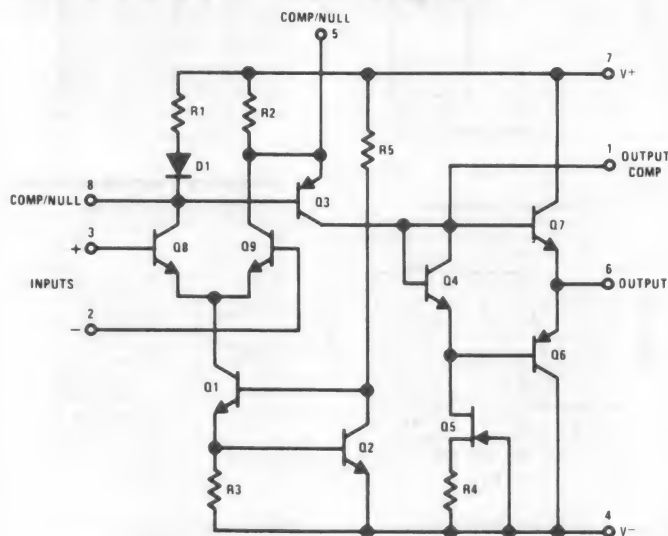

The LH0024/LH0024C's combination of wide bandwidth and high slew rate make it an ideal choice for a variety of high speed applications including active filters, oscillators, and comparators as well as many high speed general purpose applications.

The LH0024 is guaranteed over the temperature range -55°C to $+125^{\circ}\text{C}$, whereas the LH0024C is guaranteed -25°C to $+85^{\circ}\text{C}$.

Features

- Very high slew rate—500 V/ μs at $A_V = +1$
- Wide small signal bandwidth—70 MHz
- Wide large signal bandwidth—15 MHz
- High output swing— $\pm 12\text{V}$ into 1k
- Offset null with single pot
- Low input offset—2 mV
- Pin compatible with standard IC op amps

Applications Information

LAYOUT CONSIDERATIONS

The LH0024/LH0024C, like most high speed circuitry, is sensitive to layout and stray capacitance. Power supplies should be by-passed as near the device as is practicable with at least $0.01\text{ }\mu\text{F}$ disc type capacitors. Compensating capacitors should also be placed as close to device as possible.

COMPENSATION RECOMMENDATIONS

Compensation schemes recommended in Table 1 work well under typical conditions. However, poor layout and long lead lengths can degrade the performance of the LH0024 or cause the device to oscillate. Slight adjustments in the values for C_1 , C_2 , and C_3 may be necessary for a given layout. In particular, when operating at a gain of -1 , C_3 may re-

quire adjustment in order to perfectly cancel the input capacitance of the device.

When operating the LH0024/LH0024C at a gain of $+1$, the value of R_1 should be at least $1\text{ k}\Omega$.

The case of the LH0024 is electrically isolated from the circuit; hence, it may be advantageous to drive the case in order to minimize stray capacitances.

HEAT SINKING

The LH0024/LH0024C is specified for operation without the use of an explicit heat sink. However, internal power dissipation does cause a significant temperature rise. Improved offset voltage drift can be obtained by limiting the temperature rise with a clip-on heat sink such as the Thermalloy 2228B or equivalent.

Typical Applications

TTL Compatible Comparator

Offset Null

Video Amplifier

PRELIMINARY

LH0032/LH0032A/LH0032C/LH0032AC

Ultra Fast FET-Input Operational Amplifier

General Description

The LH0032/LH0032A is a high slew rate, high input impedance differential operational amplifier suitable for diverse application in fast signal handling. The high allowable differential input voltage, ease of output clamping, and high output drive capability particularly suit it for comparator applications. It may be used in applications normally reserved for video amplifiers allowing the use of operational gain setting and frequency response shaping into the megahertz region.

The LH0032's wide bandwidth, high input impedance and high output capacity make it an ideal choice for applications such as summing amplifiers in high speed D to A converters, buffers in data acquisition systems and sample and hold circuits. Additional applications include high speed integrators and video amplifiers. The LH0032 and LH0032A are guaranteed for operation over the temperature range -55°C to $+125^{\circ}\text{C}$, the LH0032C and LH0032AC are guaranteed for -25°C to $+85^{\circ}\text{C}$.

Features

- 500 V/ μs slew rate
- 70 MHz bandwidth
- $10^{12}\Omega$ input impedance
- As low as 2 mV max input offset voltage
- FET input
- Offset null with single pot
- No compensation for gains above 50
- Peak output current to 100 mA

t_R	Small Signal Rise Time	$A_V = +1$, $\Delta V_{IN} = 1V$		8	20	
t_D	Small Signal Delay Time			10	25	

Note 1. In order to limit maximum junction temperature to $+175^\circ C$, it may be necessary to operate with $V_S < \pm 15V$ when T_A or T_C exceeds specific values depending on the P_D within the device package. Total P_D is the sum of quiescent and load-related dissipation. See applications notes AN-277, "Applications of Wide-Band Buffer Amplifiers" and AN-253, "High-Speed Operational-Amplifier Applications" for a discussion of load-related power dissipation.

Note 2. LH0032AG/G are 100% production tested as specified at $25^\circ C$, $125^\circ C$, and $-55^\circ C$. LH0032ACG/CG are 100% production tested at $25^\circ C$ only. Specifications at temperature extremes are verified by sample testing, but these limits are not used to calculate outgoing quality level.

Note 3. Specification is at $25^\circ C$ junction temperature due to requirements of high-speed automatic testing. Actual values at operating temperature will exceed the value at $T_J = 25^\circ C$. When supply voltages are $\pm 15V$, no-load operating junction temperature may rise 40 – $60^\circ C$ above ambient, and more under load conditions. Accordingly, V_{OS} may change one to several mV, and I_B and I_{OS} will change significantly during warm-up. Refer to I_B and I_{OS} vs. temperature graph for expected values.

Note 4. LH0032AG/G are 100% production tested for this parameter. LH0032ACG/CG are sample tested only. Limits are not used to calculate outgoing quality levels. $\Delta V_{OS}/\Delta T$ is the average value calculated from measurements at $25^\circ C$ and T_{MAX} .

Note 5. Measured in still air 7 minutes after application of power. Guaranteed thru correlated automatic pulse testing.

Note 6. Guaranteed thru correlated automatic pulse testing at $T_J = 25^\circ C$.

Note 7. Not 100% production tested; verified by sample testing only. Limits are not used to calculate outgoing quality level.

*Guaranteed by CMRR test condition.

TL/K/5265-25

The circuit diagram shows an LHO032 operational amplifier configured as a precision half-wave rectifier. The non-inverting input (pin 6) is connected to the input signal. The inverting input (pin 5) is connected to the output (pin 10) through a feedback resistor. The output (pin 10) is also connected to the negative supply rail (V-). The op-amp's positive supply (V+) is connected to pin 12, and the negative supply (V-) is connected to pin 10. The output of the op-amp (pin 11) is connected to a 62Ω resistor, which is in series with a parallel combination of two LM113 diodes. The diodes are connected in series, with their cathodes towards the op-amp output and their anodes towards the output node. The output node is also connected to the negative supply rail (V-) through a resistor.

Applications Information

POWER SUPPLY DECOUPLING

The LH0032/LH0032A, like most high speed circuits, is sensitive to layout and stray capacitance. Power supplies should be by passed as near to pins 10 and 12 as practicable with low inductance capacitors such as 0.01 μF disc ceramics. Compensation components should also be located close to the appropriate pins to minimize stray reactances.

INPUT CURRENT

Because the input devices are FETs, the input bias current may be expected to double for each 11°C junction temperature rise. This characteristic is plotted in the typical performance characteristics graphs. The device will self-heat due to internal power dissipation after application of power thus raising the FET junction temperature 40–60°C above free-air ambient temperature when supplies are $\pm 15\text{V}$. The de-

Applications Information (Continued)

vice temperature will stabilize within 5–10 minutes after application of power, and the input bias currents measured at that time will be indicative of normal operating currents. An additional rise would occur as power is delivered to a load due to additional internal power dissipation.

There is an additional effect on input bias current as the input voltage is changed. The effect, common to all FETs, is an avalanche-like increase in gate current as the FET gate-to-drain voltage is increased above a critical value depending on FET geometry and doping levels. This effect will be noted as the input voltage of the LH0032 is taken below ground potential when the supplies are $\pm 15\text{V}$. All of the effects described here may be minimized by operating the device with $V_S \leq \pm 15\text{V}$.

These effects are indicated in the typical performance curves.

INPUT CAPACITANCE

The input capacitance to the LH0032/LH0032C is typically 5pF and thus may form a significant time constant with high value resistors. For optimum performance, the input capacitance to the inverting input should be compensated by a small capacitor across the feedback resistor. The value is

strongly dependent on layout and closed loop gain, but will typically be in the neighborhood of several picofarads.

In the non-inverting configuration, it may be advantageous to bootstrap the case and/or a guard conductor to the inverting input. This serves both to divert leakage currents away from the non-inverting input and to reduce the effective input capacitance. A unity gain follower so treated will have an input capacitance under a picofarad.

HEAT SINKING

While the LH0032/LH0032A is specified for operation without any explicit heat sink, internal power dissipation does cause a significant temperature rise. Improved bias current performance can thus be obtained by limiting this temperature rise with a small heat sink such as the Thermalloy No. 2241 or equivalent. The case of the device has no internal connection, so it may be electrically connected to the sink if this is advantageous. Be aware, however, that this will affect the stray capacitances to all pins and may thus require adjustment of circuit compensation values.

For additional applications information request Application Note AN-253.

LH0044 Series Precision Low Noise Operational Amplifiers

General Description

The LH0044 Series is a low noise, ultra-stable, high gain, precision operational amplifier family intended to replace either chopper-stabilized monolithic or modular amplifiers. The devices are particularly suited for differential mode, inverting, and non-inverting mode applications requiring very low initial offset, low offset drift, very high gain, high CMRR, and high PSRR. In addition, the LH0044 Series' low initial offset and offset drift eliminate costly and time consuming null adjustments at the systems level. The superior performance afforded by the LH0044 Series is made possible by advanced processing and testing techniques, as well as active laser trim of critical metal film resistors to minimize offset voltage and drift. Unique construction eliminates thermal feedback effects.

The LH0044 Series is an excellent choice for a wide range of precision applications including strain gauge bridges, thermocouple amplifiers, and ultrastable reference ampli-

fers. The LH0044 is guaranteed over the temperature range of -55°C to $+125^{\circ}\text{C}$, and the LH0044AC, LH0044B, and LH0044C are guaranteed from -25°C to $+85^{\circ}\text{C}$. The device is available in standard TO-5 op amp pin out and is compatible with LM108A, LM725, and LM741 type amplifiers.

Features

- Low input offset voltage 25 μV max
- Excellent long-term stability $\pm 1 \mu\text{V}/\text{month}$ max
- Low offset drift $0.5 \mu\text{V}/^{\circ}\text{C}$ max
- Very low noise $0.7 \mu\text{Vp-p}$ max 0.1 Hz to 10 Hz
- High CMRR and PSRR 120 dB min
- High open loop gain 120 dB min
- Wide common-mode range $\pm 13\text{V}$ min
- Wide supply voltage range $\pm 2\text{V}$ to $\pm 20\text{V}$

AC Electrical Characteristics $T_A = 25^\circ\text{C}$, $V_S = \pm 15\text{V}$

Parameter	Conditions	Typ	Units
Input Noise Voltage	$R_S = 1\text{ k}\Omega$, $f_O = 10\text{ Hz}$	11	$\text{nV}/\sqrt{\text{Hz}}$
	$R_S = 1\text{ k}\Omega$, $f_O = 1\text{ kHz}$	9	$\text{nV}/\sqrt{\text{Hz}}$
Slew Rate	$A_V = +1$, $R_L = 10\text{ k}\Omega$, $V_{IN} = \pm 10\text{V}$	0.06	$\text{V}/\mu\text{s}$
Large Signal Bandwidth	$A_V = +1$, $R_L = 10\text{ k}\Omega$, $V_{IN} = \pm 10\text{V}$	1	kHz
Overload Recovery Time	$A_V = +100$, $V_{IN} = -100\text{ mV}$, $\Delta V_{IN} = 200\text{ mV}$	5	μs
Small Signal Bandwidth	$A_V = +1$, $R_L = 10\text{ k}\Omega$	400	kHz
Small Signal Rise Time	$A_V = +1$, $R_L = 10\text{ k}\Omega$, $V_{IN} = 10\text{ mV}$	2.5	μs
Overshoot	$A_V = +1$, $R_L = 10\text{ k}\Omega$, $V_{IN} = 10\text{ mV}$, $C_L = 100\text{ pF}$	10	%

Note 1: All specifications apply for all device grades, at $V_S = \pm 15\text{V}$, and from T_{Min} to T_{Max} unless otherwise specified. T_{Min} is -55°C and T_{Max} is $+125^\circ\text{C}$ for the LH0044. T_{Min} is -25°C and T_{Max} is $+85^\circ\text{C}$ for the LH0044AC, LH0044B and LH0044C. Typical values are given for $T_A = 25^\circ\text{C}$.

Note 2: This parameter is not 100% tested; however, 90% of the devices are guaranteed to meet this specification after one month of operation and after initial turn-on stabilization.

Note 3: Noise is 100% tested on the LH0044AC and LH0044B only. 90% of the LH0044 and LH0044C devices are guaranteed to meet this specification.

Note 4: The inputs are shunted by back-to-back diodes for over-voltage protection. Excessive current will flow for differential input voltages in excess of 1V. Input current should be limited to less than 1 mA.

Note 5: For supply voltages less than $\pm 15\text{V}$, the absolute maximum input voltage is equal to the supply voltage.

Note 6: Refer to RETS0044AH for LH0044AH military specifications and RETS0044H for LH0044H military specifications.

Typical Performance Characteristics

Applications Information

LOW DRIFT CONSIDERATIONS

Achieving ultra-low drift in practical applications requires strict attention to board layout, thermocouple effects, and input guarding. For specific recommendations refer to AN-63 and AN-79.

A point worth stressing with regard to low drift specifications is testing of the LH0044. Simply stated—it is virtually impossible to test the device using a thermoprobe or other form of local heating. A one degree centigrade temperature gradient can account for tens of microvolts of virtual offset (or drift). The test circuit of *Figure 1* is recommended for use in a stabilized oven or continuously stirred oil bath with the entire circuit inside the oven or bath. Isothermal layout of the resistors is advised in order to minimize thermocouple induced EMF's.

OVER COMPENSATION

The LH0044 may be overcompensated in order to minimize noise bandwidth by paralleling the internal 100 pF capacitor with an external capacitor connected between pins 1 and 6. Unity gain frequency may be predicted by:

$$f = \frac{4 \times 10^{-5}}{100 \text{ pF} + C_{\text{ext}} \text{ pF}} (\text{Hz})$$

COMPENSATION

For closed loop gains in excess of 10, no external components are required for frequency stability. However, for gains of 10 or less, a 0.01 μF disc capacitor is recommended between pin 7 (V^+) and pin 8 (Comp). An improvement in ac PSRR will also be realized by use of the 0.01 μF capacitor.

OFFSET NULL

In general, further nulling of LH0044 is neither necessary nor recommended. For most applications the specified initial offset is sufficient.

However, for those applications requiring additional null, an obvious temptation might be to place a pot between pins 1 and 8 with the wiper returned to V^+ . This technique will usually result in reduced gain and increased offset drift due to mismatch in the TCR of the pot and R1 and R2. The technique is, therefore, not generally recommended.

The recommended technique for offset nulling the LH0044 is shown in *Figure 2*. Null is accomplished in A_2 and all errors are divided by the closed loop gain of the LH0044. Additional offset and drift incurred due to the use of A_2 is less than $1 \mu\text{V/V}$ for V^+ and V^- changes and $0.01 \mu\text{V}/^\circ\text{C}$ drift for the values shown in *Figure 2*.

LH0045/LH0045C Two Wire Transmitter

General Description

The LH0045/LH0045C Two Wire Transmitters are linear integrated circuits designed to convert the voltage from a sensor to a current, and send it through to a receiver, utilizing the same simple twisted pair as the supply voltage.

The LH0045 and LH0045C contain an internal reference designed to power the sensor bridge, a sensitive input amplifier, and an output current source. The output current scale can be adjusted to match the industry standards of 4.0 mA to 20 mA or 10 mA to 50 mA.

Designed for use with various sensors, the LH0045/LH0045C will interface with thermocouples, strain gauges, or thermistors. The use of the power supply leads as the signal output eliminates two or three extra wires in remote signal applications. Also, current output minimizes susceptibility to voltage noise spikes and eliminates line drop problems.

The LH0045/LH0045C is intended to fulfill a wide variety of process control, instrumentation, and data acquisition applications. The LH0045 is guaranteed over the temperature range of -55°C to $+125^{\circ}\text{C}$; whereas the LH0045C is guaranteed from -25°C to $+85^{\circ}\text{C}$.

Features

- High sensitivity $> 10 \mu\text{A}/\mu\text{V}$
- Low input offset voltage 1.0 mV
- Low input bias current 2.0 nA
- Single supply operation 10V to 50V
- Programmable bridge reference (LH0045G) 5.0V to 30V
- Non-interactive span and null adjust
- Over compensation capability
- Supply reversal protection

Equivalent Schematic

*Note: Pins shown are for the 12 pin to 8 ("G") package.

Applications Information

CIRCUIT DESCRIPTION AND OPERATION

A simplified schematic of the LH0045/LH0045C is shown in Figure 1. Differential amplifier, A_2 converts very low level signals to an output current via transistor Q1. Reference voltage diode D1 is used to supply voltage for operation of A_2 and to bias an external bridge. Current source I_1 minimizes fluctuation in the bridge reference voltage due to changes in V_S .

In normal operation, the LH0045/LH0045C is used in conjunction with an external bridge comprised of R_{B1} through R_{B4} . The bridge resistors in conjunction with bridge return resistor, R_5 , bias A_2 in its linear region and sense the input signal; e.g. R_{B4} might be a strain sensitive resistor in a strain gauge bridge. R_T is adjusted to purposely unbalance the bridge for 4.0 mA output (null) for zero signal input. This is accomplished by forcing 2.5 μ A more through R_{B3} than R_{B4} .

The 2.5 μ A imbalance causes a voltage rise of $(2.5 \mu\text{A}) \times (100\Omega)$ or 250 μ V at the top of R_{B3} . Terminal L2 may be viewed as the output of an op amp whose closed loop gain is approximately $R_F/R_{B3} = 1600$.

The 250 μ V rise at the top of R_{B3} causes a voltage drop of $(1600) \times (250 \mu\text{V})$ or -0.4V across R_9 . An output current, I_S , equal to $0.4\text{V}/R_9$ or 4.0 mA is thus established in Q1. If R_{B4} is now decreased by 1.0Ω (due to application of a strain force), a -1.0 mV change in input voltage will result. This causes L2 to drop to -2.0V . The output current would then be $2.0\text{V}/100\Omega$ or 20 mA (Full Scale). If R_{B3} is a resistor of the same material as R_{B4} but not subjected to the strain, temperature drift effects will be equal in the two legs and will cancel.

In actual practice the loading effects of R_{B2} on the gain (span) and R_F on output current must be taken into account.

THERMAL CONSIDERATIONS

The power output transistor of the LH0045 is thermally isolated from the signal amplifier, A_2 . Nevertheless, a change in the power dissipation will cause a change in the temperature of the package and thus may cause amplifier drift. These temperature excursions may be minimized by careful heat sinking to hold the case temperature equal to the ambient. With the TO-8 (G) package this is best accomplished by a clip-on heat sink such as the Thermalloy #2240A or the Wakefield #215-CB. The case is electrically isolated from the circuit.

In addition, the power change can be minimized by operating the device from relatively high supply voltages in series with a relatively high load resistance. When the signal forces the supply current higher, the voltage across the device will be reduced and the internal power dissipation kept nearly equal to the low current, high voltage condition.

For example, take the case of a 4.0 mA to 20 mA transmitter with a 24V supply and a 100 Ω load resistance. The power at 4.0 mA is $(23.6\text{V}) \times (4.0 \text{ mA}) = 94.4 \text{ mW}$ while at full scale the power is $(22\text{V}) \times (20 \text{ mA}) = 440 \text{ mW}$. The net change in power is 345 mW. This change in power will cause a change in temperature and thus a change in offset voltage of A_2 .

If the optimum load resistance of 800 Ω (from Figure 2) is used, the power at null is $[24\text{V} - (4.0 \text{ mA}) \times (800\Omega)] (4.0 \text{ mA}) = 83 \text{ mW}$. The power at full scale is $[24\text{V} - (20 \text{ mA}) \times (800\Omega)] (20 \text{ mA}) = 160 \text{ mW}$. The net change is 77 mW. This change is significantly less than without the resistor.

TL/K/5556-9

Applications Information (Continued)

If the supply voltage is increased to 48V and the load resistance chosen to be the optimum value from Figure 2 (1.95k), then the power at null is $[48V - (4.0 \text{ mA}) \times (1.95k)] (4.0 \text{ mA}) = 160.8 \text{ mW}$ and the power at full scale is $[48 - (20) \times (1.95k)] (20 \text{ mA}) = 180 \text{ mW}$ for a net change of 19.2 mW.

TL/K/5556-10

FIGURE 2. Optimum Load Resistance vs Supply Voltage

Note that the optimized load resistance is actually the sum of the line resistance, receiver resistances and added external load resistance. However, in many applications the line resistance and receiver resistances are negligible compared to the added external load resistance and thus may be omitted in calculations.

AUXILIARY PINS

The LH0045 has several auxiliary pins designed to provide the user with enhanced flexibility and performance. The following is a discussion of possible uses for these pins.

Programmable V_{REF} —Pins 5 and 6

The LH0045G provides pins 5 and 6 to allow the user to program the value of the reference voltage. The factory trimmed 10V value is obtained by leaving 5 and 6 open. A short between 5 and 6 will program the reference to a nominal 5.1V.

A resistor or pot may be placed between pin 5 and common (pin 3) to obtain reference voltages between 10V and 30V or between pin 5 and pin 7 for reference voltages below 10V. Increased reference voltage might be useful to extend the positive common mode range or to accommodate transducers requiring higher supply voltage. A plot of resistance between pin 5 and pin 3 versus V_{REF} is given in the typical electrical characteristics section. V_{REF} may be adjusted about its nominal value by arranging a pot from V_{REF} to common and feeding a resistor from the wiper into pin 5 so that it may either inject or extract current. Lastly, pin 5 may be used as a nominal 1.7V reference point, if care is taken not to unduly load it with either DC current or capacitance. Obviously, higher supply voltages must be used to obtain the higher reference values. The minimum supply voltage to reference voltage differential is about 4.0V.

Bridge Return

An applications resistor is provided in the LH0045 with a nominal value of 1.0 kΩ. The primary application for the resistor is to maintain the minimum common mode input voltage (1.0V) required by the signal amplifier, A_2 . A typical input application might utilize a strain gauge or thermistor bridge where the resistance of the sensor is 100Ω. Since only 1.0 mA may be drawn from V_{REF} , the 1.0 kΩ bridge return resistor is used to bias A_2 in its linear region as shown in Figure 3.

TL/K/5556-11

FIGURE 3. Use of Bridge Return

Over Compensation—Pin 8

Over compensation of the signal amplifier, A_2 , may be desirable in DC applications where the noise-bandwidth must be minimized. A capacitor should be placed between pin 8 and pin 3, common.

Typically,

$$f_{3 \text{ db}} = \frac{1}{2 \pi R (C_1 + C_{EXT})}$$

where:

$R = 400 \text{ M}\Omega$

$C_1 = \text{Internal Compensation Capacitor} = 100 \text{ pF}$

$C_{EXT} = \text{External (overcompensation) Capacitor}$

Input Guard—Pins 9 and 12

Pins 9 and 12 have no internal connection whatever and thus need not be used. In some critical low current applications there may be an advantage to running a guard conductor between the inputs and the adjacent pins to intercept stray leakage currents. Pins 9 and 12 may be connected to this guard to simplify the PC board layout and allow the guard to continue under the device. (See AN-63 for further discussion of guarding techniques.)

NULL AND SPAN ADJUSTMENTS

Most applications of the LH0045 will require potentiometers to trim the initial tolerances of the sensor, the external resistors and the LH0045 itself. The preferred adjustment proce-

Applications Information (Continued)

ture is to stimulate the sensor, alternating between two known values, such as zero and full scale. The span and null are adjusted by monitoring the output current on a chart recorder, meter, or oscilloscope. A full scale stimulus is applied to the sensor and the span potentiometer adjusted for the desired full scale. Then, to adjust the null, apply a zero percent signal to the sensor and adjust the null potentiometer for the desired zero percent current indication.

If it is impractical to cycle the sensor during the calibration procedure, the signal may be simulated electrically with two cautions: 1) the calibration signal must be floating and 2) the calibration thus achieved does not account for sensor inaccuracies and/or errors in the signal generator.

SENSOR SELECTION

Generally it is easiest to use an insulated sensor. If it is necessary to use a grounded sensor, the power supply must be isolated from chassis ground to avoid extraneous circulating currents.

DESIGN EXAMPLE

There are numerous circuit configurations that may be utilized with the LH0045. The following is intended as a general design example which may be extended to specific cases.

Circuit Requirements

Output Characteristics

- 0% = 4.0 mA (NULL)
- 100% = 20 mA (SPAN = 16 mA)
- Supply Voltage = 24V

Input (Sensor) Characteristics

- $V_{IN} = 100$ mV (Full Scale)
- $V_{IN} = 0$ mV (Zero Scale)
- Source Impedance $\leq 1.0\Omega$

General Characteristics

- $0^\circ\text{C} \leq T_A \leq +75^\circ\text{C}$
- Overall Accuracy $\leq 0.5\%$

TL/K/5556-12

FIGURE 4. Design Example Circuit

Selection of R_F

Input bias current to the LH0045C is guaranteed less than 10 nA. Furthermore, the change in I_B over the temperature range of interest is typically under 1.0 nA. If I_2 SPAN is selected to be 1.0 μA (1000 ΔI_B) errors due to $\Delta I_B/\Delta T$ will be less than 0.1%. For SPAN = 16 mA.

$$V_{SPAN} = \Delta V_1 = -(16 \text{ mA})(R_9) = -1.6\text{V}$$

where R_9 = Internal Current Set Resistor = 100 Ω .

For I_2 SPAN = 1.0 μA ,

$$R_F = \frac{V_{SPAN}}{I_2 \text{ SPAN}} = \frac{-1.6\text{V}}{1.0 \mu\text{A}} = 1.6\text{M}$$

$$R_F = 1.6 \text{ M}\Omega$$

Note: For applications with DC gain (ratio of feedback and input resistance) less than 8, it is recommended that a Schottky barrier diode be connected between pin 11 (cathode) and pin 3 (anode). This prevents the possibility of latch up resulting from the inverting input being forced beyond the amplifier supply voltage during power up.

Selection of R_{B1} and R_{B2}

The minimum input common mode voltage, V_{MIN} required at the pin 10 input of A_2 is 1.0V. Furthermore, the maximum open loop supply current (I_{SOL}) drawn by the LH0045 is 3.0 mA. That leaves $I_{MIN} = 4.0 \text{ mA} - 3.0 \text{ mA} = 1.0 \text{ mA}$ left to bias the bridge at null. Hence:

$$R_{B2} \geq \frac{V_{MIN}}{I_{MIN}} = \frac{1.0\text{V}}{1.0 \text{ mA}} = 1.0 \text{ k}\Omega$$

And,

$$\frac{V_{REF} R_{B2}}{R_{B1} + R_{B2}} = 1.0\text{V}$$

$$R_{B1} = R_{B2} \frac{V_{REF} - 1.0\text{V}}{1.0\text{V}} = 1.0\text{k} (5.1 - 1.0)$$

$$R_{B1} \approx 4.0 \text{ k}\Omega$$

Alternatively, an LM113, 1.22V reference diode, or an op amp such as the LM108 may be used to bias the signal amplifier, A_2 , as shown in Figure 5. These techniques have the advantage of lowering the impedance seen at pin 10.

Selection of R_{OS}

R_{OS} is selected to provide the null current of 4.0 mA, V_1 NULL = 4.0 mA \times 100 Ω = 0.4V. From previous calculations we know that $V_{MIN} = 1.0\text{V}$. The voltage pin 11, V_2 is:

$$V_2 = V_{MIN} + V_{OS} \approx V_{MIN}$$

for $V_{IN} = 0\text{V}$

Hence, the current required to generate the null voltage, I_2 NULL is:

$$I_2 \text{ NULL} = \frac{V_{MIN} - V_1 \text{ NULL}}{R_F} = \frac{1.0\text{V} - (-0.4\text{V})}{1.6 \text{ M}\Omega} = 0.875 \mu\text{A}$$

This current must be provided by R_{OS} from V_{REF} ; hence:

$$R_{OS} = \frac{V_{REF} - V_{MIN}}{I_2 \text{ NULL}}$$

Applications Information (Continued)

ERROR BUDGET ANALYSIS

Errors Due to Change in V_{REF} (ΔV_{REF})

There are several factors which could cause a change in V_{REF} . First, as the ambient temperature changes, a V_{REF} drift of ± 0.2 mV/°C might be expected. Secondly, supply voltage variations could cause a 0.5 mV/V change in V_{REF} . Lastly, self-heating due to power dissipation variations can cause drift of the reference.

An overall expression for change in V_{REF} is:

$$\Delta V_{REF} = \underbrace{[(\theta)(\Delta P_{DISS}) + \Delta T_A] \frac{\Delta V_{REF}}{\Delta T}}_{\text{Thermal Effects}} + \underbrace{\frac{\Delta V_{REF}}{\Delta V_S} (\Delta V_S)}_{\text{Supply Voltage Effects}}$$

Where:

θ = Thermal resistance, either junction-to-ambient or junction-to-case

ΔP_{DISS} = Change in avg. power dissipation

ΔT_A = Change in ambient temperature

$\frac{\Delta V_{REF}}{\Delta T}$ = Reference voltage drift (in mV/°C)

$\frac{\Delta V_{REF}}{\Delta V_S}$ = Line regulation of V_{REF}

Several steps may be taken to minimize the bracketed terms in the equation above. For example, operating the LH0045G with a heat sink reduces the thermal resistance from $\theta_{JA} = 83^\circ\text{C/W}$ to $\theta_{JC} = 60^\circ\text{C/W}$. The ΔP_{DISS} term may be significantly reduced using the power minimization technique described under "Thermal Considerations". For the design example, ΔP_{DISS} is reduced from 384 mW to 77 mW ($R_L = 800\Omega$). Evaluating the LH0045G with a heat sink and $R_L = 800\Omega$ yields:

$$\Delta V_{REF} = \left(\frac{60^\circ\text{C}}{\text{W}} (0.077\text{W}) + 75^\circ\text{C} \right) \left(\frac{0.2\text{mV}}{^\circ\text{C}} \right) + \frac{0.5\text{mV}}{\text{V}} (16\text{V})$$

$$\Delta V_{REF} = 24\text{mV}$$

An expression for error in the output current due to ΔV_{REF} is:

$$\frac{\Delta I_S}{I_{SPAN}} (\%) = 100 \frac{(K)(R_{OS})(\Delta V_{REF}) - (1-K)(\Delta V_{REF})(R_F)}{(R_9)(R_{OS})(I_{SPAN})}$$

Where:

ΔV_{REF} = Total change in V_{REF}

$$K = \frac{R_{B2}}{R_{B1} + R_{B2}}$$

R_9 = Current set resistor

I_{SPAN} = Change in output current from 0% to 100%

For example, $\Delta V_{REF} = 24$ mV, $K = 0.2$, $R_9 = 100\Omega$, $I_{SPAN} = 16$ mA. Hence, a 0.12% worst case error might be expected in output currents due to ΔV_{REF} effects.

Error Due to V_{OS} Drift

One of the primary causes of error in I_S is caused by V_{OS} drift. Drift may be induced either by self heating of the device or ambient temperature changes. The input offset voltage drift, $\Delta V_{OS}/\Delta T$, is nominally 3.3 $\mu\text{V}/^\circ\text{C}$ per millivolt of initial offset. An expression for the total temperature dependent drift is:

$$\Delta V_{OS} = [(\theta)(\Delta P_{DISS}) + \Delta T_A] \frac{\Delta V_{OS}}{\Delta T}$$

Where:

θ = Thermal resistance either junction-to-ambient or junction-to-case

ΔP_{DISS} = Change in average power dissipation

ΔT_A = Change in ambient temperature

The bracketed term may be minimized by heat sinking and using the power minimization technique described under "Thermal Considerations". For the LH0045G design example, $\Delta V_{OS} = 0.352$ mV under ambient conditions and 0.263 mV using a heat sink and $R_L = 800\Omega$.

The error in output current due to ΔV_{OS} is:

$$\begin{aligned} \frac{\Delta I_S}{I_{SPAN}} (\text{in } \%) &= 100 \times \frac{\Delta V_{OS}}{V_{IN} (\text{FULL SCALE})} \\ &= 100 \times \frac{R_F}{(R)(R_9)(I_{SPAN})} \end{aligned}$$

For the design example, $\Delta V_{OS} = 0.263$ mV, $V_{IN} (\text{Full Scale}) = 100$ mV. Hence, 0.26 mV \div 100 mV or 0.26% worst case error could be expected in output current effects.

Errors Due to Changes in R_9

The temperature coefficient of R_9 (TCR) will produce errors in the output current. Changes in R_9 may be caused by self-heating of the device or by ambient temperature changes.

$$\frac{\Delta I_S}{I_{SPAN}} (\text{in } \%) = 100 \frac{\Delta R_9}{\Delta T} (\theta P_{DISS} + \Delta T_A)$$

Where:

θ = Thermal resistance either from junction-to-ambient or junction-to-case

ΔP_{DISS} = Change in average power dissipation

Applications Information (Continued)

ΔT_A = Change in ambient temperature

$$\frac{\Delta R_9}{\Delta T} = \text{TCR of } R_9$$

Using the LH0045G design example, $\Delta R_9/\Delta T = 0.03\%/^{\circ}\text{C}$, hence a 3.2% worst case error in output current might be expected for operation without a heat sink over the temperature range.

Heat sinking the device and using $R_L = 800\Omega$, reduces $\Delta I_S/I_{SPAN}$ to 2.3%.

The error analysis indicates that the internal current set resistor, R_9 , is inadequate to satisfy high accuracy design criterion. In these instances, an external 100Ω resistor should be substituted for R_9 .

Obviously, the TCR of the resistor should be low. Metal film or wire-wound resistors are the best choice offering TCR's less than 10 ppm/ $^{\circ}\text{C}$ versus 50 ppm/ $^{\circ}\text{C}$ typical drift for R_9 .

External Causes of Error

The components external to the LH0045 are also critical in determining errors. Specifically, the composition of resistors R_{B1} , R_{OS} , R_F , R , etc. in the design example will influence both drift and long term stability.

In particular, resistors and potentiometers of wire wound construction are recommended. Also, metal-film resistors with low TCR (≤ 10 ppm/ $^{\circ}\text{C}$) may be used for fixed resistor applications.

Error Analysis Summary

The overall errors attributable to the LH0045 may be minimized using heat sinking, and utilization of an external load resistor. Although R_L reduces the compliance of the circuit, its use is generally advisable in precision applications. External components should be selected for low TCR and long term stability.

The design example errors, using an external 100Ω wire wound resistor for R_9 equal:

$$\frac{\Delta I_S}{I_{SPAN}} = \underbrace{0.12\%}_{\Delta V_{REF}} + \underbrace{0.26\%}_{\Delta V_{OS}} + \underbrace{0.08\%}_{\Delta R_9} = 0.46\%$$

SOCKETS AND HEAT SINKS

Mounting sockets, test sockets and heat sinks are available for the G package.

The following or their equivalents are recommended:

Sockets:

G — 12-Lead TO-8: Barnes Corp. #MGX-12
Textool #212-100-323

Heat Sinks:

G — 12-Lead TO-8: Thermalloy #2240A
Wakefield #215-CB

Definition of Terms

Input Offset Voltage, V_{OS} : The voltage which must be applied between the input terminals through equal resistances to obtain 4.0 mA of supply (output) current.

Input Bias Current, I_B : The average of the two input currents.

Input Offset Current, I_{OS} : The difference in the current into the two input terminals when the supply (output) current is 4.0 mA.

Input Resistance, R_{IN} : The ratio of the change in input voltage to the change in input current at either input with the other input connected to 1.0 V_{DC} .

Open Loop Transconductance, g_{MOL} : The ratio of the supply (output) current SPAN to the input voltage required to produce that SPAN.

Open Loop Output Resistance, R_{OUT} : The ratio of a specified supply (output) voltage change to the resulting change in supply (output) current at the specified current level.

Common Mode Rejection Ratio, CMRR: The ratio of the change in input offset voltage to the peak-to-peak input voltage range.

Power Supply Rejection Ratio, PSRR: The ratio of the change in input offset voltage to the change in supply (output) voltage producing it.

Input Voltage Range, V_{IN} : The range of voltages on the input terminals for which the device operates within specifications.

Open Loop Supply Current, I_S : The supply current required with the signal amplifier A_2 biased off (inverting input positive, non-inverting input negative) and no load on the V_{REF} terminal.

This represents a measure of the minimum low end signal current.

Reference Voltage Line Regulation, $\Delta V_{REF}/\Delta V_S$: The ratio of the change in V_{REF} to the peak-to-peak change in supply (output) voltage producing it.

Reference Voltage Load Regulation, $\Delta V_{REF}/\Delta I_{REF}$: The change in V_{REF} for a stipulated change in I_{REF} .

LH0061/LH0061C 0.5 Amp Wide Band Operational Amplifier

General Description

The LH0061/LH0061C is a wide band, high speed, operational amplifier capable of supplying currents in excess of 0.5 ampere at voltage levels of $\pm 12V$. Output short circuit protection is set by external resistors, and compensation is accomplished with a single external capacitor. With a suitable heat sink the device is rated at 20W.

The wide bandwidth and high output power capabilities of the LH0061/LH0061C make it ideal for such applications as AC servos, deflection yoke drivers, capstan drivers, and audio amplifiers. The LH0061 is guaranteed over the temperature range $-55^{\circ}C$ to $+125^{\circ}C$; whereas, the LH0061C is guaranteed from $-25^{\circ}C$ to $+85^{\circ}C$.

Features

- Output current 0.5A
- Wide large signal bandwidth 1 MHz
- High slew rate 70V/ μ s
- Low standby power 240 mW
- Low input current 300 nA Max

LH0062/LH0062C High Speed FET Operational Amplifier

General Description

The LH0062/LH0062C is a precision, high speed FET input operational amplifier with more than an order of magnitude improvement in slew rate and bandwidth over conventional FET IC op amps. In addition it features very closely matched input characteristics, very high input impedance, and ultra low input currents with no compromise in noise, common mode rejection ratio or open loop gain. The device has internal unity gain frequency compensation, thus assuring stability in all normal applications. This considerably simplifies its application, since no external components are necessary for operation. However, unlike most internally compensated amplifiers, external frequency compensation may be added for optimum performance. For inverting applications, feed-forward compensation will boost the slew rate to over 120 V/ μ s and almost double the bandwidth. (See LB-2, LB-14, and LB-17 for discussions of the application of feed-forward techniques). Over-compensation can be used with the amplifier for greater stability when maximum bandwidth is not needed. Further, a single capacitor can be added to reduce the 0.1% settling time to under 1 μ s. In addition it is free of latch-up and may be simply offset nulled with negligible effect on offset drift or CMRR.

The LH0062 is designed for applications requiring wide bandwidth, high slew rate and fast settling time while at the same time demanding the high input impedance and low input currents characteristic of FET inputs. Thus it is particularly suited for such applications as video amplifiers, sample/hold circuits, high speed integrators, and buffers for A/D conversion and multiplex system. The LH0062 is specified for the full military temperature range of -55° to $+125^{\circ}\text{C}$ while the LH0062C is specified to operate over a -25°C to $+85^{\circ}\text{C}$ temperature range.

Features

- High slew rate 70 V/ μ s
- Wide bandwidth 15 MHz
- Settling time (0.1%) 1 μ s
- Low input offset voltage 2 mV
- Low input offset current 1 pA
- Wide supply range $\pm 5\text{V}$ to $\pm 20\text{V}$
- Internal 6 dB/octave frequency compensation
- Pin compatible with std IC op amps (TO-5 pkg)

Input Noise Current	BW = 10 Hz to 10 kHz		<0.1			<0.1		pArms

Note 1: For supply voltages less than $\pm 15\text{V}$, the absolute maximum input voltage is equal to the supply voltage.

Note 2: Inputs are protected from excessive voltages by back-to-back diodes. Input currents should be limited to 1 mA.

Note 3: Unless otherwise specified, these specifications apply for $\pm 5\text{V} \leq V_S \leq \pm 20\text{V}$ and $-55^\circ\text{C} \leq T_A \leq +125^\circ\text{C}$ for the LH0062 and $-25^\circ\text{C} \leq T_A \leq +85^\circ\text{C}$ for the LH0062C. Typical values are given for $T_A = 25^\circ\text{C}$. Power supplies should be bypassed with $0.1\text{ }\mu\text{F}$ ceramic capacitors.

Note 4: Input currents are a strong function of temperature. Due to high speed testing they are specified at a junction temperature $T = 25^\circ\text{C}$, self heating will cause an increase in current in manual tests. 25°C spec is guaranteed by testing at 125°C .

Note 5: Refer to RETS0062X for LH0062D and LH0062H military specifications.

LH0082 Optical Communication Receiver/Amplifier

General Description

The LH0082 is a general purpose, low-noise, fiber-optic receiver, which may also be used as a fast current to voltage converter, or as a high speed voltage amplifier. The circuit includes a wide-bandwidth FET-input amplifier, a 2.4V reference, a comparator with hysteresis, and all the necessary resistors and capacitors for feedback and coupling, all integrated in a hermetic dual-in-line package. The large gain-bandwidth of the preamp enables fast response even with high capacitance photodiodes. A separate analog output permits the reception of analog signals to 20 MHz via a fiber-optic link. The internal comparator converts a low level analog signal to a CMOS/TTL compatible logic signal at data rates up to 5 Mbits/s NRZ. The LH0082 can be used with an external comparator at data rates to 40 Mbits/s.

Features

- Single 4.5V to 12V supply
- 600 MHz unity gain bandwidth
- Low noise
- Low edge jitter
- $<10^{-9}$ bit error rate

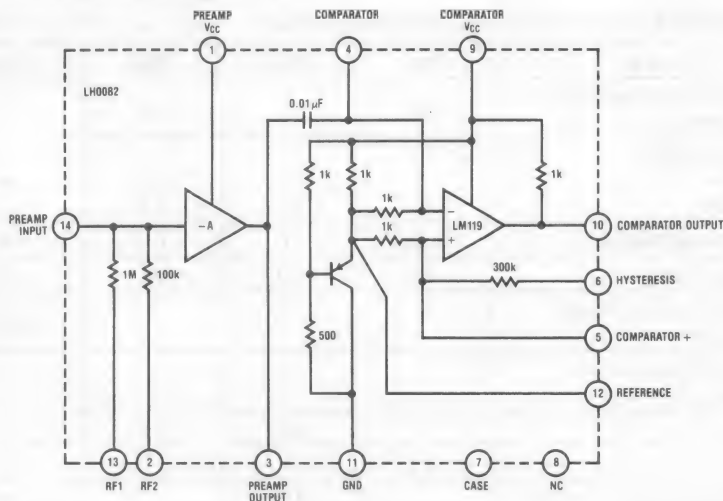

- Low input bias current
- Pin selectable sensitivity: -45 dBm/ -35 dBm*
- CMOS/TTL compatibility
- Can be used with photodiodes, PIN photodiodes, phototransistors, avalanche photodiodes, and photomultipliers
- Hermetic dual-in-line metal package
- Highly versatile building block
- >21 dB dynamic range

Applications

- Data terminals
- Secure communication
- Peripheral control/communication
- Video transmission
- Wideband amplifier
- High speed current to voltage converter
- Fiber-optic repeater
- Video amplifier
- Industrial machine control

*Assumes 0.5 A/W PIN diode input

i_N	Equivalent Input Noise Current (10 Hz to 10 MHz)		300		pA RMS
	Low Sensitivity: $R_F = 100$ k Ω , (see Figure 4) Input Power for 10^{-9} BER (Bit Rate = 2 Mbit NRZ)		800		nW
t_r, t_f	Analog Output Rise or Fall Time Maximum Data Rate, NRZ, Digital Output		50 5		ns Mbit/s
P_N	Noise Equivalent Power		10		nW
i_N	Equivalent Input Noise Current (10 Hz to 10 MHz)		3		nA RMS
I_S	Total Supply Current (High or Low Sensitivity)		35		mA

Note 1: Refer to RETS0082D for LH0082D/883 and LH0082D-MIL specifications.

Note 2: For military temperature range, see RETS0082D.

DIGITAL EDGE JITTER

A potential problem in digital transmission systems is "edge jitter". Jitter is related to the system rise time and receiver noise and can be approximated by the following equation:

$$\text{RMS edge jitter} = \frac{\text{System rise time (10\%–90\%)}}{(p/p_{\text{signal voltage}} \div \text{RMS noise voltage in receiver})}$$

For a 5 Mbits/s NRZ operation using a 0.5 A/W PIN diode, the LH0082 requires a 2 μW peak optical power. This translates to 120 mV peak-to-peak signal voltage. Following through this equation the RMS edge jitter of the LH0082 is inconsequential at approximately 0.1 μs .

Applications Information

The gain-bandwidth of the LH0082 preamp is nearly 2 GHz, thus good bypassing of the supply voltage is necessary; a $3.3\ \mu\text{F}$ tantalum capacitor in parallel with a $0.01\ \mu\text{F}$ ceramic disc is recommended, placed as close as possible to the device pins.

Careful shielding of pins 2, 13 and 14 is necessary if the LH0082 is used in a high noise environment. Minimize stray capacitance to pin 14 from ground, V_{CC} or pin 3 to avoid slowing overall circuit response. Choose the lowest capac-

itance photodiode possible for the application. When using phototransistors, only the collector-base junction should be used for fastest response. Additional sensitivity may be gained by using a phototransistor in the transistor mode, although this will result in slower circuit response, and poor DC stability due to beta multiplication of the dark current of the phototransistor. Avoid capacitive loading at the output of the comparator to achieve maximum data rates.

Avalanche photodiodes can be used for improved sensitivity and speed. Overall speed is limited by the internal comparator. Use of an external comparator such as the LM160 will enable the full speed capability to be realized. This requires the use of an additional power supply, see Figure 5.

For operations at higher data rates, Figure 5 shows the use of an external comparator to enable speeds to 50 Mbit NRZ. Figure 6, 7 and 8 demonstrate interfacing techniques to avalanche photodiodes and phototransistors.

With a few additional components, the LH0082 can be used as a repeater as shown in Figure 9. Interfacing to a micro-computer-bus, (Figure 10), is also easy when the LH0082 is teamed with an INS8250 Asynchronous Communications Element. This provides a full duplex link capable of bit rates to 56 kbits/s NRZ.

Analog data can be sent along a fiber-optic cable via digital means, (Figure 11). Low temperature drift can be obtained in the analog mode, by using the circuit shown in Figure 12.

LH0086/LH0086C

Digitally-Programmable-Gain Amplifier

General Description

The LH0086 is a self-contained, high-accuracy, digitally-programmable-gain amplifier. It consists of a FET-input operational amplifier, a precision resistor ladder, and a digitally-programmable switch network. A three-bit TTL-compatible digital input selects accurate gain settings of 1, 2, 5, 10, 20, 50, 100, or 200.

The LH0086 exhibits low offset voltage, high input impedance, fast settling, high power supply rejection ratio, and excellent gain accuracy and gain non-linearity.

The LH0086 is specified for operation from -55°C to $+125^{\circ}\text{C}$. The LH0086C is specified from -25°C to $+85^{\circ}\text{C}$. Both devices are hermetically sealed in a 14-lead dual-in-line metal package.

Features

- 0.01% maximum gain accuracy at gain = 1
- 0.005% typical gain non-linearity
- 1 ppm/ $^{\circ}\text{C}$ typical gain drift
- $10^{10}\Omega$ input impedance
- 80 dB minimum PSRR.
- TTL-compatible digital inputs
- 2 μs settling to 0.01%

Applications

- Data acquisition systems
- Auto range DVMs
- Adaptive servo loops

Simplified Schematic and Connection Diagrams

Note 1: Improper supply power-on sequence may damage the device. See Power Supply Connection Section under Applications Information.

Note 2: for supply voltages less than $\pm 15V$ the maximum input voltage is equal to the supply voltage.

Note 3: Due to short production test time, these parameters are specified at junction temperature, $T_J = 25^\circ\text{C}$. In normal operation the junction temperature rises above the ambient temperature, T_A , as a result of the internal power dissipation, P_D . $T_J = T_A + \theta_{JA} \times P_D$ where θ_{JA} is the thermal resistance from junction to ambient (typically $65^\circ\text{C}/\text{W}$).

Note 4: The input bias currents are junction leakage currents which approximately double for every 10°C increase in junction temperature.

Note 5: Refer to RETS0086D for LH0086D military specifications.

Applications Information

Theory of Operation

The LH0086 is a digitally programmable gain amplifier with 3-bit digital gain control. It contains a FET-input operational amplifier, a precision resistor ladder, and a digitally programmable switch network.

The LH0086 was designed for use in a non-inverting configuration, thus the following discussion covers the LH0086 as used as a non-inverting amplifier. The gain of the LH0086 is given by the familiar gain equation of a non-inverting amplifier.

$$A_V = 1 + \frac{R_F}{R_S}$$

Each gain step is set by the ratio of the ladder resistors. The resistor ladder is constructed with high stability, low temperature-coefficient resistors precision laser-trimmed to the required values. FET switches are used to select the desired ratio. Since the FET switches are in series with the operational amplifier input, their "on resistance" and temperature drift do not degrade amplifier accuracy. The FET switches are selected by a 1 of 8 decoder, by applying the proper logic levels at digital inputs D0, D1, and D2. The gains are set as given in Table I.

TABLE I. Gain-Control Codes

Gain	D2	D1	D0
1	0	0	0
2	0	0	1

Power Supply Connection

Proper power supply connections are shown in Figure 1. The power supplies should be bypassed to ground as close as possible to device supply pins. For most applications, the bypass capacitor should be 0.1 μ F.

*GERMANIUM OR SCHOTTKY

FIGURE 1. Power Supply and Ground Connections

Care must be taken in the power-on sequence. The LH0086 may suffer irreversible damage if the V^+ supply is applied prior to the powering on of the V^- supply. In most applications using dual-tracking supplies and with the device supply pins adequately bypassed, this will not present a problem. If this cannot be guaranteed, a germanium or Schottky protection diode should be connected between the digital ground pin and the V^- pin as shown in Figure 1.

Grounding Considerations

Care should be taken in the connection of digital and analog grounds. Digital switching currents can introduce noise on the analog ground pin. If possible, both grounds should go to a ground plane beneath the device, otherwise each ground should be run separately to a single point ground. The idea is to keep digital current from passing through the analog ground line. If long ground leads are used, diode clamps should be placed as close to the device as possible (Figure 1).

Programmable Attenuator

The LH0086 may be used as a programmable attenuator when connected as in Figure 2. The accuracy of this attenuator will be typically 0.1%.

Note: Max. $V_{IN} = \pm 11$ Volts.

FIGURE 2. Programmable Attenuator

TL/K/5657-5

Applications Information (Continued)

TABLE II. Attenuator Codes

D2	D1	D0	Attenuation
0	0	0	1
0	0	1	2
0	1	0	5
0	1	1	10
1	0	0	20
1	0	1	50
1	1	0	100
1	1	1	200

Inverting Mode

The LH0086 may be used in the inverting mode, however, there are several design considerations.

1. Input resistance is low at high gains (see gain chart for input resistance at each gain).
2. Each gain step gets a one subtracted from the non-inverting gain. (See inverting gain chart for available gains.)
3. The first gain step (digital code of 000) cannot be used because the output will remain at virtual ground regardless of the input.

FIGURE 3. LH0086 Inverting Gain Configuration

Remote Output Sense

The V_{OUT} sense pin of the LH0086 should be connected at the load in order to eliminate errors due to lead resistance. In any case the output sense and output force must be tied together at some point. See Figure 4.

FIGURE 4. Remote Output Sense FIGURE 5. Offset Adjustment

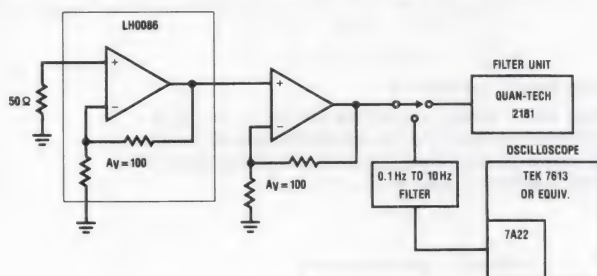

FIGURE 6. Noise Measurement Circuit

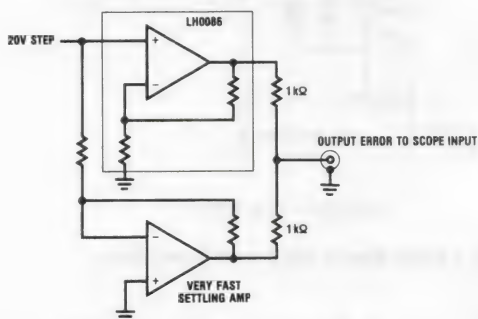

FIGURE 7. Settling Time Test Circuit

Definition of Terms

V_{OS} **Offset Voltage:** The voltage that must be applied to force the output to 0 volts.

I_B **Input Bias Current:** The current into Pin 7 with the device connected in the non-inverting configuration.

R_{IN} **Input Resistance:** The ratio of the change in input voltage to the change in input current on either input with the other grounded.

V_{IN} **Input Voltage Range:** The voltage range for which the device is operational.

PSRR **Power Supply Rejection Ratio:** The ratio of the specified change in supply voltage to the change in input offset voltage over this range.

A_V **Voltage Gain:** The ratio of output voltage change to the input voltage change producing it.

Gain Error: The deviation in percent between the ideal voltage gain and the value obtained when the device is configured for that gain.

Gain Non-Linearity: The deviation of the gain from a straight line drawn through the end-points expressed as a percent of full scale (10V for operation with $\pm 15V$ supplies). For testing purposes it is the difference between positive swing gain (0V to 10V) and average gain ($-10V$ to 10V) or between negative swing gain (0V to $-10V$) and average gain.

V_O **Output Voltage Swing:** The peak output voltage swing referenced to ground into specified load.

I_{O(SC)} **Output Short-Circuit Current:** The current supplied by the device with the output connected directly to ground.

R_O **Closed Loop Output Resistance:** The ratio of change in output voltage to change to output current at a specific gain.

V_S **Supply Voltage Range:** The supply voltage range for which the device is operational.

I_S **Supply Current:** The current required from the supply to operate the device with no load and with the analog as well as the digital inputs at 0V.

P_D **Power Dissipation:** The power dissipated in the device with no load and with the analog as well as the digital inputs at 0V.

V_{IH} **Digital "1" Input Voltage:** Minimum voltage required at the digital input to guarantee a high logic state.

V_{IL} **Digital "0" Input Voltage:** The current into a digital input at specified logic level.

$\Delta V_{OS}/\Delta T$ **Average Input Offset Voltage Drift:** The ratio of input offset voltage change from 25°C to either temperature extreme divided by the temperature range.

$\Delta A_V/\Delta T$ **Average Gain Temperature Coefficient:** The ratio in gain from 25°C to either temperature extreme divided by the temperature range.

BW **Bandwidth:** The frequency at which the voltage gain is reduced to 3 dB below the low frequency value.

PBW **Power Bandwidth:** Maximum frequency for which the output swing is a large signal sine-wave without noticeable distortion.

SR **Slew Rate:** The internally limited rate of change in output voltage with a large amplitude step function applied at the input.

t_S **Settling Time:** The time between the initiation of an input step function and the time when the output voltage has settled to within a specified error band of the final output voltage.

Gain Switching Time: The time between the initiation of a gain logic change and the time when the final gain switches are closed. It includes overdrive recovery time, but not settling to final value.

e_N **Equivalent Input Noise Voltage:** The rms or peak noise voltage referred to the input (RTI) over a specified frequency band.

i_N **Equivalent Input Noise Current:** The rms or peak noise current referred to the input (RTI) over a specified frequency band.

LH0101/LH0101C, LH0101A/LH0101AC Power Operational Amplifier

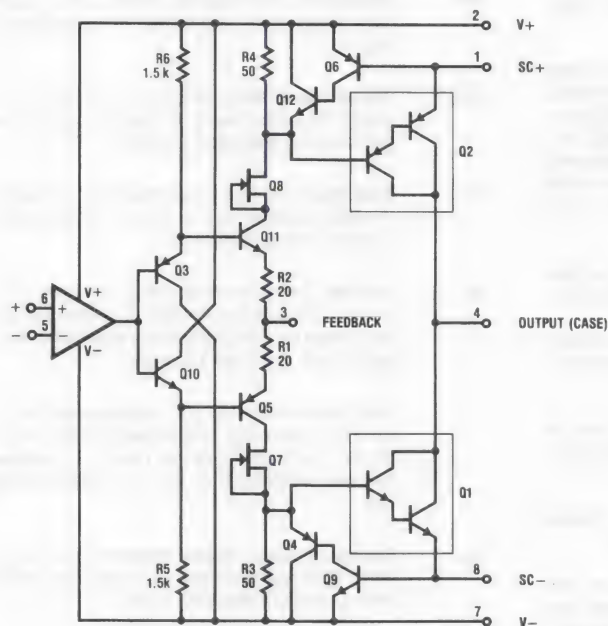

General Description

The LH0101 is a wideband power operational amplifier featuring FET inputs, internal compensation, virtually no crossover distortion, and rapid settling time. These features make the LH0101 an ideal choice for DC or AC servo amplifiers, deflection yoke drives, programmable power supplies, and disk head positioner amplifiers. The LH0101 is packaged in an 8 pin TO-3 hermetic package, rated at 60 watts with a suitable heat sink.

Features

- 5 Amp peak, 2 Amp continuous output current
- 300 kHz power bandwidth
- 850 mW standby power ($\pm 15V$ supplies)
- 300 pA input bias current
- 10 V/ μ s slew rate
- Virtually no crossover distortion
- 2 μ s settling time to 0.01%
- 5 MHz gain bandwidth

Note 1: Specification is at $T_A = 25^\circ C$. Actual values at operating temperature may differ from the $T_A = 25^\circ C$ value. When supply voltages are $\pm 15V$, quiescent operating junction temperature will rise approximately $20^\circ C$ without heat sinking. Accordingly, V_{OS} may change 0.5 mV and I_B and I_{OS} will change significantly during warm-ups. Refer to the I_B vs. temperature and power dissipation graphs for expected values. Power supply voltage is $\pm 15V$. Temperature tests are made only at extremes.

Note 2: Change in offset voltage with dissipated power is due entirely to average device temperature rise and not to differential thermal feedback effects. Test is performed without any heat sink.

Note 3: At light loads, the output swing may be limited by the second stage rather than the output stage. See the application section under "Output swing enhancement" for hints on how to obtain extended operation.

Note 4: These parameters are sample tested to 10% LTPD.

Note 5: Refer to RETS0101AK for the LH0101AK military specifications and RETS0101K for the LH0101K military specifications.

Application Hints

Input Voltages

The LH0101 operational amplifier contains JFET input devices which exhibit high reverse breakdown voltages from gate to source or drain. This eliminates the need for input clamp diodes, so that high differential input voltages may be applied without a large increase in input current. However, neither input voltage should be allowed to exceed the negative supply as the resultant high current flow may destroy the unit.

Exceeding the negative common-mode limit on either input will cause a reversal of the phase to the output and force the amplifier output to the corresponding high or low state. Exceeding the negative common-mode limit on both inputs will force the amplifier output to a high state. In neither case does a latch occur since raising the input back within the common-mode range again puts the input stage and thus the amplifier in a normal operating mode.

Exceeding the positive common-mode limit on a single input will not change the phase of the output however, if both inputs exceed the limit, the output of the amplifier will be forced to a high state.

These amplifiers will operate with the common-mode input voltage equal to the positive supply. In fact, the common-mode voltage may exceed the positive supply by approximately 100 mV, independent of supply voltage and over the full operating temperature range. The positive supply may therefore be used as a reference on an input as, for example, in a supply current monitor and/or limiter.

With the LH0101 there is a temptation to remove the bias current compensation resistor normally used on the non-inverting input of a summing amplifier. Direct connection of the inputs to ground or a low-impedance voltage source is not recommended with supply voltages greater than 3V. The potential problem involves loss of one supply which can cause excessive current in the second supply. Destruction of the IC could result if the current to the inputs of the device is not limited to less than 100 mA or if there is much more than 1 μ F bypass on the supply buss.

Although difficulties can be largely avoided by installing clamp diodes across the supply lines on every PC board, a conservative design would include enough resistance in the input lead to limit current to 10 mA if the input lead is pulled to either supply by internal currents. This precaution is by no means limited to the LH0101.

Layout Considerations

When working with circuitry capable of resolving pico-ampere level signals, leakage currents in circuitry external to the op amp can significantly degrade performance. High quality insulation is a must (Kel-F and Teflon rate high). Proper cleaning of all insulating surfaces to remove fluxes and other residues is also required. This includes the IC package as well as sockets and printed circuit boards. When operating in high humidity environments or near 0°C, some form of surface coating may be necessary to provide a moisture barrier.

The effects of board leakage can be minimized by encircling the input circuitry with a conductive guard ring operated at a potential close to that of the inputs.

Electrostatic shielding of high impedance circuitry is advisable.

Error voltages can also be generated in the external circuitry. Thermocouples formed between dissimilar metals can cause hundreds of microvolts of error in the presence of temperature gradients.

Since the LH0101 can deliver large output currents, careful attention should be paid to power supply, power supply bypassing and load currents. Incorrect grounding of signal inputs and load can cause significant errors.

Every attempt should be made to achieve a single point ground system as shown in the figure below.

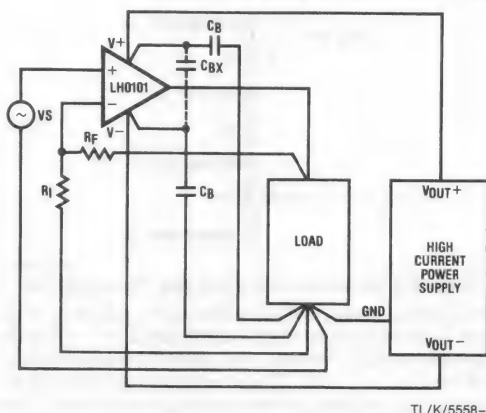

FIGURE 1. Single-Point Grounding

Bypass capacitor C_{BX} should be used if the lead lengths of bypass capacitors C_B are long. If a single point ground system is not possible, keep signal, load, and power supply from intermingling as much as possible. For further information on proper grounding techniques refer to "Grounding and Shielding Techniques in Instrumentation" by Morrison, and "Noise Reduction Techniques in Electronic Systems" by Ott (both published by John Wiley and Sons).

Leads or PC board traces to the supply pins, short-circuit current limit pins, and the output pin must be substantial enough to handle the high currents that the LH0101 is capable of producing.

Short Circuit Current Limiting

Should current limiting of the output not be necessary, SC+ should be shorted to V+ and SC- should be shorted to V-. Remember that the short circuit current limit is dependent upon the total resistance seen between the supply and current limit pins. This total resistance includes the desired resistor plus leads, PC Board traces, and solder joints.* Assuming a zero TCR current limit resistor, typical temperature coefficient of the short circuit will be approximately .3%.

*Short circuit current will be limited to approximately $\frac{0.6}{RSC}$.

Application Hints (Continued)

Thermal Resistance

The thermal resistance between two points of a conductive system is expressed as:

$$\theta_{12} = \frac{T_1 - T_2}{P_D} \text{ } ^\circ\text{C/W}$$

where subscript order indicates the direction of heat flow. A simplified heat transfer circuit for a cased semiconductor and heat sink system is shown in the figure below.

The circuit is valid only if the system is in thermal equilibrium (constant heat flow) and there are, indeed, single specific temperatures T_J , T_C and T_S (no temperature distribution in junction, case, or heat sink). Nevertheless, this is a reasonable approximation of actual performance.

TL/K/5558-B

FIGURE 2. Semiconductor-Heat Sink Thermal Circuit

The junction-to-case thermal resistance θ_{JC} specified in the data sheet depends upon the material and size of the package, die size and thickness, and quality of the die bond to the case or lead frame. The case-to-heat sink thermal resistance θ_{CS} depends on the mounting of the device to the heat sink and upon the area and quality of the contact surface. Typical θ_{CS} for a TO-3 package is 0.5 to 0.7°C/W, and 0.3 to 0.5°C/W using silicone grease.

The heat sink to ambient thermal resistance θ_{SA} depends on the quality of the heat sink and the ambient conditions.

Cooling is normally required to maintain the worst case operating junction temperature T_J of the device below the specified maximum value $T_{J(MAX)}$. T_J can be calculated from known operating conditions. Rewriting the above equation, we find:

$$\theta_{JA} = \frac{T_J - T_A}{P_D} \text{ } ^\circ\text{C/W}$$

Where: $P_D (V_S - V_{OUT})_{OUT} + |V_+ - (V_-)|I_Q$
for a DC Signal

$\theta_{JA} = \theta_{JC} + \theta_{CS} + \theta_{SA}$ and $V_S =$ Supply Voltage
 θ_{JC} for the LH0101 is about 2°C/W.

Stability and Compensation

As with most amplifiers, care should be taken with lead dress, component placement and supply decoupling in order to ensure stability. For example, resistors from the output to an input should be placed with the body close to the input to minimize "pickup" and maximize the frequency of the feedback pole by minimizing the capacitance from the input to ground.

A feedback pole is created when the feedback around any amplifier is resistive. The parallel resistance and capacitance from the input device (usually the inverting input) to ac

ground set the frequency of the pole. In many instances the frequency of this pole is much greater than the expected 3 dB frequency of the closed loop gain and consequently there is negligible effect on stability margin. However, if the feedback pole is less than approximately six times the expected 3 dB frequency a lead capacitor should be placed from the output to the input of the op amp. The value of the added capacitor should be such that the RC time constant of this capacitor and the resistance it parallels is greater than or equal to the original feedback pole time constant.

Some inductive loads may cause output stage oscillation. A .01 μF ceramic capacitor in series with a 10 Ω resistor from the output to ground will usually remedy this situation.

TL/K/5558-9

FIGURE 3. Driving Inductive Loads

Capacitive loads may be compensated for by traditional techniques. (See "Operational Amplifiers: Theory and Practice" by Roberge, published by Wiley):

TL/K/5558-10

FIGURE 4. R_C and C_C Selected to Compensate for Capacitive Load

A similar but alternative technique may be used for the LH0101:

TL/K/5558-11

FIGURE 5. Alternate Compensation for Capacitive Load

Application Hints (Continued)

Output Swing Enhancement

When the feedback pin is connected directly to the output, the output voltage swing is limited by the driver stage and not by output saturation. Output swing can be increased as shown by taking gain in the output stage as shown in High Power Voltage Follower with Swing Enhancement below. Whenever gain is taken in the output stage, as in swing enhancement, either the output stage, or the entire op amp must be appropriately compensated to account for the additional loop gain.

Typical Applications

LH4101/LH4101C Wideband High Current Operational Amplifier

General Description

The LH4101 is a high slew rate, FET input, wideband operational amplifier designed for applications that require an op amp to provide up to 200 mA peak and 100 mA continuous output current. This feature eliminates the need for a buffer to provide the additional current drive not available with most wideband op amps.

Designed for use with minimum external circuitry, the LH4101 provides internal compensation for unity gain stability and all the gain set resistors for most popular gain settings, as well as internal supply bypass capacitors. These features minimize the circuit's sensitivity to external layout conditions. These features are provided in a 24 pin hermetic dual in-line package.

Features

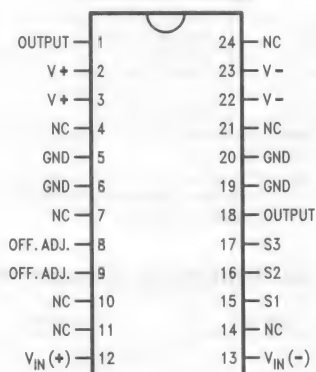

- 45 MHz bandwidth
- $10^{12}\Omega$ input impedance
- Pin strappable gain settings of 1, 2, 3, 4, -1, -2, -3
- Unity gain stable
- Internal supply bypassing
- 100 mA continuous output current
- 24 pin hermetic DIP
- Directly drives 50 Ω loads

The LH4101's wide bandwidth, programmable gain settings, and high output current make it an ideal choice for fast buffering applications such as video distribution. It is also appropriate for use in summing amplifiers, sample and hold circuits, and high speed integrators.

Applications Information

Power Supply Bypassing

The LH4101 will perform well in most circuit boards even without external supply bypassing; however, it is recommended that some bulk bypassing be provided. One 10 μ F electrolytic on each supply is recommended. Proximity to the device pins is not critical, but the bypass will be most effective if located within an inch of the part.

Input Capacitance

The input capacitance to the LH4101 is typically 5 pF and for source impedances greater than 100 Ω , the input time constant should be considered.

Gain Settings

The LH4101 provides internal gain set resistors for most popular gain settings. A chart is provided to assist in determining the proper pins to connect to achieve these gains. The internal gain resistors are trimmed and matched to insure the gain accuracy to 0.8% typically. The LH4101 can operate at other gain settings, but the user must supply additional gain set resistors external to the part.

-3	S3 to V_{out}	17 to 18	

Typical Applications

Unity Gain Follower

The LH4101 can be used as a unity gain follower to provide output current to drive 50Ω or 75Ω coax cable directly. By shorting pins 15, 16 and 18, a follower circuit is configured as seen in *Figure 1a*. This configuration features a band-

width greater than 40 MHz with an input signal of $1.0 V_{p-p}$ and greater than 16 MHz with a $5 V_{p-p}$ input signal. This is all achieved without any external components. *Figures 1b* and *1c* show the small and large signal pulse responses, respectively.

Non-Inverting Amplifier

To configure the LH4101 as a non-inverting amplifier with a gain of 4, short pins 17 to 18 and 15 to 19, as shown in Figure 2a. Again, no external components are necessary. This configuration provides a bandwidth of 25 MHz with an

input sine wave of $1.0 V_{p-p}$ and a bandwidth of 10 MHz with an input of $5 V_{p-p}$ while providing 100 mA of output current. This eliminates the need of an additional buffer in the circuit to provide the output current to drive large loads. Figures 2b and 2c show the small and large signal pulse responses, respectively.

FIGURE 2c

Differential Amplifier

To configure the LH4101 as a differential amplifier, two additional $1 k\Omega$ resistors are required. Figure 3 shows this con-

figuration, where $V_O = V_1 - V_2$. The gain accuracy of this circuit is dependent upon the gain accuracy of the additional $1 k\Omega$ resistors.

PRELIMINARY

LH4104/LH4104C Fast Settling High Current Operational Amplifier

General Description

The LH4104 is a fast settling high current Bi-Fet op amp designed for applications that require a fast settling time of 500 ns to 0.01% and 100 mA continuous output current. The high output current eliminates the need for a buffer to provide the additional current drive not available in most operational amplifiers. The operational amplifier also features a gain bandwidth product of 18 MHz and a slew rate of 40V/ μ s.

Designed for use with minimum external circuitry, the LH4104 provides internal compensation for unity gain stability as well as internal supply bypass capacitors. These features minimize the circuit's sensitivity to external layout conditions.

Features

- 500 ns settling time to 0.01% for a 10V step
- 100 mA continuous output current
- 18 MHz gain bandwidth product
- Internal supply bypassing
- Unity gain stable

Applications

- Cable Drivers
- High Speed Ramp Generators
- DAC Output Amplifiers
- Fast Buffers
- Sample and Holds
- Fast Integrators

Typical Performance Characteristics

TL/K/8840-4

TL/K/8840-5

Applications Information

POWER SUPPLY BYPASSING

The LH4104 will perform well in most circuit boards even without external supply bypassing; however it is recommended that some bulk bypassing be provided to maintain optimum settling time. A 0.1 μ F disc ceramic capacitor and 1 μ F tantalum capacitor on each supply is recommended. Place the bypass capacitors close to the amplifiers supply pins.

COMPENSATION

To minimize the effects of input capacitance at the LH4104's inverting input and any additional layout capacitance, an external compensation capacitor must be used. The compensation capacitor (C1) used in Figure 2 (Test Circuit Section) is typically 66 pF. The optimum value for the compensation capacitor depends on the application circuit and the board layout.

INPUT BIAS CURRENT

The input devices are JFETs, and will normally have input bias (I_B) currents in the tens of picoamps. However, these

currents vary with temperature and input voltage range. I_B will normally double with each 11°C rise in junction temperature.

LAYOUT PRECAUTIONS

Grounding and circuit layout are extremely important in preserving the settling time of the LH4104. It is important to use single point ground returns for inputs, loads, and feedback components and to keep the returns short. Compensation components should be located close to the appropriate pins to minimize stray reactances. Keep the system's digital signals (or any other signals with fast rise times) separated from the amplifier. If such signals are too close to the amplifier, they can couple capacitively to the amplifier's inputs, resulting in undesirable signals at the output.

PRESERVING AND VERIFYING THE LH4104'S FAST SETTLING TIME

To realize optimum settling performance in circuits using the LH4104, both the design and layout must be meticulous. Application note AN-428, "Preserving and Verifying the

Applications Information (Continued)

LF400's Fast Settling Time", explains the required design and measurement techniques. Although this application note was written for the LF400, it suggests good guidelines and is directly applicable to the LH4104. Only the sections covering supply bypassing and output load limitations should be ignored. This is because the LH4104 has internal bypassing capacitors and substantially greater output drive current than the LF400. The suggested circuits require only small and straightforward modifications; even the printed circuit board layout can be easily modified to accept the footprint of the LH4104 without impacting setting time.

PROTECTION SCHEMES FOR THE LH4104

The LH4104 has similar input characteristics of National Semiconductor's BI-FET™ family of operational amplifiers. As such, designing with this part requires that several precautions are observed which are uncharacteristic of other op amps. Application Note AN-447 covers these caveats in greater detail for the whole product family. (The LH4104's input stage shares its topology with the LF400.)

NEVER LEAVE AN INPUT UNATTENDED!

If an input to the LH4104 is left open circuited (or connected to an analog multiplexer in a high impedance state), the input bias current will be drawn from the very small parasitic input capacitance (<10 pF). This capacitor will rapidly charge up to the power supply rail at a rate of $dv/dt = I_{BIAS}/C_{IN}$. Since the LH4104 is a capable of large output currents and has no internal current limiting, it will easily be destroyed by excessive power dissipation if such an input condition exists while driving a low impedance load (e.g. 50Ω).

To avoid this condition in circuits where the LH4104 is buffering the FET switch of an analog multiplexer, one must connect a resistor between the input and ground to provide a bias current path. This will invariably degrade the effective input impedance of the device, so a large resistor is desirable.

For example, selecting a $1\text{ M}\Omega$ resistor will result in a harmless 25 mV output signal during the "deselected" state (for the worst case bias current of 25 nA). Increasing this resistor will increase the output signal for the deselected state; decreasing it will reduce this signal while degrading the input impedance. Depending on the user's circuit specifications, a compromise must be selected. This resistor will not introduce an increase in the effective offset voltage during the "selected" state because the input is driven by a low impedance source.

POWER SUPPLY SEQUENCING

Adding the clamp diodes shown in Figure 1 not only protects the inputs from transients when the circuit is operating, but protects them as power is being applied to the circuit. Because the parasitic transistor appears when the input voltage is less than the negative supply, applying the positive supply or input voltage before the negative supply is applied can cause this problem. For this reason, it is always recom-

mended that the negative supply be turned on **first**, if the supplies can be turned on independently.

Also, even if the input stage is well protected with clamp diodes and current limiting, the inputs should not be allowed to be heavily unbalanced (for example, one input at ground and the other at the rail) for extended periods of time (for example, many hours). The long-term effects of an unbalanced differential pair are increased offset voltage and offset current.

TL/K/8840-13

FIGURE 1. Clamping Inputs of Op Amp

V_{OS} ADJUSTMENT

Offset voltage can be nulled using a 56K resistor and a 25K potentiometer connected to pins 3 and 7 as shown in Figure 3. Bypassing the V_{OS} adjust pins with $0.1\text{ }\mu\text{F}$ capacitors will help to avoid noise pickup. When not used for offset adjustment, pins 3 and 7 can often be left open, but to minimize the possibility of noise pickup the unused V_{OS} trim pins should be connected to ground or V^- .

PRELIMINARY

LH4105/LH4105C Precision Fast Settling High Current Operational Amplifier

General Description

The LH4105 is a fast settling high current Bi-Fet op amp designed for applications that require a fast settling time of 500 ns to 0.01% and 100 mA continuous output current. The high output current eliminates the need for a buffer to provide the additional current drive not available in most operational amplifiers. The operational amplifier also features a gain bandwidth product of 18 MHz and a slew rate of 40V/ μ s.

Designed for use with minimum external circuitry, the LH4105 provides internal compensation for unity gain stability as well as internal supply bypass capacitors. These features minimize the circuit's sensitivity to external layout conditions.

Features

- 500 μ V offset voltage
- 500 ns settling time to 0.01% for a 10V step
- 100 mA continuous output current
- Internal supply bypassing
- Unity gain stable

Applications

- Cable Drivers
- High Speed Ramp Generators
- DAC Output Amplifiers
- Fast Buffers
- Sample and Holds
- Fast Integrators

Applications Information

POWER SUPPLY BYPASSING

The LH4105 will perform well in most circuit boards even without external supply bypassing; however it is recommended that some bulk bypassing be provided to maintain optimum settling time. A 0.1 μF disc ceramic capacitor and 1 μF tantalum capacitor on each supply is recommended. Place the bypass capacitors close to the amplifiers supply pins.

COMPENSATION

To minimize the effects of input capacitance at the LH4105's inverting input and any additional layout capacitance, an external compensation capacitor must be used. The compensation capacitor (C_1) used in *Figure 2* (Test Circuit Section) is typically 66 pF. The optimum value for the compensation capacitor depends on the application circuit and the board layout.

INPUT BIAS CURRENT

The input devices are JFETs, and will normally have input bias (I_B) currents in the tens of picoamps. However, these currents vary with temperature and input voltage range. I_B will normally double with each 11°C rise in junction temperature.

LAYOUT PRECAUTIONS

Grounding and circuit layout are extremely important in preserving the settling time of the LH4105. It is important to use single point ground returns for inputs, loads, and feedback components and to keep the returns short. Compensation components should be located close to the appropriate pins to minimize stray reactances. Keep the system's digital signals (or any other signals with fast rise times) separated from the amplifier. If such signals are too close to the amplifier, they can couple capacitively to the amplifier's inputs, resulting in undesirable signals at the output.

PRESERVING AND VERIFYING THE LH4104'S FAST SETTLING TIME

To realize optimum settling performance in circuits using the LH4105, both the design and layout must be meticulous. Application note AN-428, "Preserving and Verifying the LF400's Fast Settling Time", explains the required design and measurement techniques. Although this application note was written for the LF400, it suggests good guidelines and is directly applicable to the LH4105. Only the sections covering supply bypassing and output load limitations should be ignored. This is because the LH4105 has internal bypassing capacitors and substantially greater output drive current than the LF400. The suggested circuits require only small and straightforward modifications; even the printed circuit board layout can be easily modified to accept the footprint of the LH4105 without impacting settling time. In addition, bypassing offset adjust pins 3 and 7 with 0.1 μF capacitors will minimize noise pickup and preserve the settling time.

PROTECTION SCHEMES FOR THE LH4104

The LH4105 has similar input characteristics of National Semiconductor's BI-FET™ family of operational amplifiers. As such, designing with this part requires that several precautions are observed which are uncharacteristic of other op amps. Application Note AN-447 covers these caveats in greater detail for the whole product family. (The LH4105's input stage shares its topology with the LF400.)

NEVER LEAVE AN INPUT UNATTENDED

If an input to the LH4105 is left open circuited (or connected to an analog multiplexer in a high impedance state), the input bias current will be drawn from the very small parasitic input capacitance (<10 pF). This capacitor will rapidly charge up to the power supply rail at a rate of $dv/dt = I_{BIAS}/C_{IN}$. Since the LH4105 is capable of large output currents and has no internal current limiting, it will easily be destroyed by excessive power dissipation if such an input condition exists while driving a low impedance load (e.g. 50 Ω).

To avoid this condition in circuits where the LH4105 is buffering the FET switch of an analog multiplexer, one must connect a resistor between the input and ground to provide a bias current path. This will invariably degrade the effective input impedance of the device, so a large resistor is desirable.

For example, selecting a 1 M Ω resistor will result in a harmless 25 mV output signal during the "deselected" state (for the worst case bias current of 25 nA). Increasing this resistor will increase the output signal for the deselected state; decreasing it will reduce this signal while degrading the input impedance. Depending on the user's circuit specifications, a compromise must be selected. This resistor will not introduce an increase in the effective offset voltage during the "selected" state because the input is driven by a low impedance source.

POWER SUPPLY SEQUENCING

Adding the clamp diodes shown in *Figure 1* not only protects the inputs from transients when the circuit is operating, but protects them as power is being applied to the circuit. Because the parasitic transistor appears when the input voltage is less than the negative supply, applying the positive supply or input voltage before the negative supply is applied can damage the device. For this reason, it is always recommended that the negative supply be turned on **first**, if the supplies can be turned on independently.

Also, even if the input stage is well protected with clamp diodes and current limiting, the inputs should not be allowed to be heavily unbalanced (for example, one input at ground and the other at the rail) for extended periods of time (for example, many hours). The long-term effects of an unbalanced differential pair are increased offset voltage and offset current.

LM10/LM10B(L)/LM10C(L) Op Amp and Voltage Reference

General Description

The LM10 series are monolithic linear ICs consisting of a precision reference, an adjustable reference buffer and an independent, high quality op amp.

The unit can operate from a total supply voltage as low as 1.1V or as high as 40V, drawing only 270 μ A. A complementary output stage swings within 15 mV of the supply terminals or will deliver ± 20 mA output current with ± 0.4 V saturation. Reference output can be as low as 200 mV. Some other characteristics of the LM10 are

■ input-offset voltage	2.0 mV (max)
■ input-offset current	0.7 nA (max)
■ input-bias current	20 nA (max)
■ reference regulation	0.1% (max)
■ offset-voltage drift	2 μ V/ $^{\circ}$ C
■ reference drift	0.002%/°C

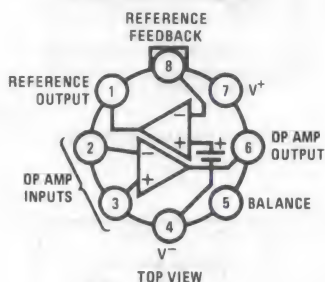

The circuit is recommended for portable equipment and is completely specified for operation from a single power cell. In contrast, high output-drive capability, both voltage and current, along with thermal overload protection, suggest it in demanding general-purpose applications.

The device is capable of operating in a floating mode, independent of fixed supplies. It can function as a remote comparator, signal conditioner, SCR controller or transmitter for analog signals, delivering the processed signal on the same line used to supply power. It is also suited for operation in a wide range of voltage- and current-regulator applications, from low voltages to several hundred volts, providing greater precision than existing ICs.

This series is available in the three standard temperature ranges, with the commercial part having relaxed limits. In addition, a low-voltage specification (suffix "L") is available in the limited temperature ranges at a cost savings.

Reference drift			0.002			0.003		%/°C
Supply current			260	400 500		280	500 570	μA μA

Note 1: The Input voltage can exceed the supply voltages provided that the voltage from the input to any other terminal does not exceed the maximum differential input voltage and excess dissipation is accounted for when $V_{\text{IN}} < V^-$.

Note 2: The maximum, operating-junction temperature is 150°C for the LM10, 100°C for the LM10B(L) and 85°C for the LM10C(L). At elevated temperatures, devices must be derated based on package thermal resistance.

Note 3: Internal thermal limiting prevents excessive heating that could result in sudden failure, but the IC can be subjected to accelerated stress with a shorted output and worst-case conditions.

Note 4: These specifications apply for $V^- \leq V_{\text{CM}} \leq V^+ - 0.85\text{V (1.0V)}$, $1.2\text{V (1.3V)} < V_S \leq V_{\text{MAX}}$, $V_{\text{REF}} = 0.2\text{V}$ and $0 \leq I_{\text{REF}} \leq 1.0\text{ mA}$, unless otherwise specified: $V_{\text{MAX}} = 40\text{V}$ for the standard part and 6.5V for the low voltage part. Normal typeface indicates 25°C limits. **Boldface type indicates limits and altered test conditions for full-temperature-range operation**; this is -55°C to 125°C for the LM10, -25°C to 85°C for the LM10B(L) and 0°C to 70°C for the LM10C(L). The specifications do not include the effects of thermal gradients ($\tau_1 \approx 20\text{ ms}$), die heating ($\tau_2 \approx 0.2\text{ s}$) or package heating. Gradient effects are small and tend to offset the electrical error (see curves).

Note 5: For $T_J > 90^\circ\text{C}$, I_{OS} may exceed 1.5 nA for $V_{\text{CM}} = V^-$. With $T_J = 125^\circ\text{C}$ and $V^- \leq V_{\text{CM}} \leq V^+ + 0.1\text{V}$, $I_{\text{OS}} \leq 5\text{ nA}$.

Note 6: This defines operation in floating applications such as the bootstrapped regulator or two-wire transmitter. Output is connected to the V^+ terminal of the IC and input common mode is referred to V^- (see typical applications). Effect of larger output-voltage swings with higher load resistance can be accounted for by adding the positive-supply rejection error.

Note 7: Refer to RETS10X for LM10H military specifications.

Application Hints

With heavy amplifier loading to V^- , resistance drops in the V^- lead can adversely affect reference regulation. Lead resistance can approach 1Ω . Therefore, the common to the reference circuitry should be connected as close as possible to the package.

Definition of Terms

Input offset voltage: That voltage which must be applied between the input terminals to bias the unloaded output in the linear region.

Input offset current: The difference in the currents at the input terminals when the unloaded output is in the linear region.

Input bias current: The absolute value of the average of the two input currents.

Input resistance: The ratio of the change in input voltage to the change in input current on either input with the other grounded.

Large signal voltage gain: The ratio of the specified output voltage swing to the change in differential input voltage required to produce it.

Shunt gain: The ratio of the specified output voltage swing to the change in differential input voltage required to produce it with the output tied to the V^+ terminal of the IC. The load and power source are connected between the V^+ and V^- terminals, and input common-mode is referred to the V^- terminal.

Common-mode rejection: The ratio of the input voltage range to the change in offset voltage between the extremes.

Supply-voltage rejection: The ratio of the specified supply-voltage change to the change in offset voltage between the extremes.

Line regulation: The average change in reference output voltage over the specified supply voltage range.

Load regulation: The change in reference output voltage from no load to that load specified.

Feedback sense voltage: The voltage, referred to V^- , on the reference feedback terminal while operating in regulation.

Reference amplifier gain: The ratio of the specified reference output change to the change in feedback sense voltage required to produce it.

Feedback current: The absolute value of the current at the feedback terminal when operating in regulation.

Supply current: The current required from the power source to operate the amplifier and reference with their outputs unloaded and operating in the linear range.

LM11/LM11C/LM11CL Operational Amplifiers

General Description

The LM11 is a precision dc amplifier combining the best features of existing bipolar and FET op amps. It is similar to the LM108A, except that input currents have been reduced by more than a factor of ten. Offset voltage and drift have also been improved.

Compared to FETs, the device provides inherently lower offset voltage and offset voltage drift, along with at least an order of magnitude better long-term stability. Low frequency noise is also somewhat reduced. Bias current is significantly lower even under laboratory conditions, and its low drift makes compensation practical. Offset current is almost unmeasurable. Although not as fast as FETs, it does have a much lower power drain. This low dissipation has the added advantage of eliminating warm up time in critical applications.

Typical characteristics for 25°C (–55°C to 125°C) are:

- offset voltage: 100 μV (200 μV)
- bias current: 25 pA (65 pA)
- offset current: 0.5 pA (3 pA)
- temperature drift: 1 $\mu\text{V}/^\circ\text{C}$
- long-term stability: 10 $\mu\text{V}/\text{year}$

The LM11 is internally compensated, but external compensation can be added for improved frequency stability, particularly with capacitive loads. Offset voltage balancing is also provided, with the balance range determined by a low-resistance potentiometer.

Otherwise, the device is the electrical equivalent of the LM108, except that the negative common-mode limit is 0.6V less, performance is specified down to $\pm 2.5\text{V}$ and the guaranteed output drive has been increased to $\pm 2\text{ mA}$. The input noise is somewhat higher, but amplifier noise is obscured by resistor noise with higher source resistances.

This monolithic IC has obviously applications as electrometer amplifiers, charge integrators, analog memories, low frequency active filters or for frequency shaping in slow servo loops. It can be substituted for existing circuits to provide improved performance or eliminate trimming operations. The greater precision can also be used to extend the dynamic range of logarithmic amplifiers, light meters and solid-state particle detectors.

The LM11 is manufactured with standard bipolar processing using super-gain transistors.

Output Short-Circuit Current	$T_J = 150^{\circ}\text{C}$		± 15					mA

Note 1: The inputs are shunted with back-to-back diodes for overvoltage protection. Therefore, excessive current will flow if a differential input voltage in excess of 1V is applied between the inputs unless some limiting resistance is used. In addition, a 2 k Ω minimum resistance in each input is advised to avoid possible latch up initiated by supply reversals.

Note 2: The maximum operating-junction temperature is 150°C for the LM11 and 85°C for the LM11C(L). Devices must be derated at $150^{\circ}\text{C}/\text{W}$ for the metal can and $155^{\circ}\text{C}/\text{W}$ for the plastic DIP. The metal can has a thermal resistance of $45^{\circ}\text{C}/\text{W}$ for the junction to case if a heat sink is used.

Note 3: Current limiting protects the output when it is shorted to ground or any voltage less than the supplies. With continuous overloads, package dissipation must be taken into account and heat sinking provided when necessary.

Note 4: These specifications apply for $V^- + 2\text{V}$ (**2.5V**) $\leq V_{CM} \leq V^+ - 1\text{V}$ and $\pm 2.5\text{V} \leq V_S \leq \pm 20\text{V}$, unless otherwise specified. Normal typeface indicates 25°C limits. **Boldface type indicates limits for full-temperature range operation.** This is $-55^{\circ}\text{C} \leq T_J \leq 125^{\circ}\text{C}$ for the LM11 and $0^{\circ}\text{C} \leq T_J \leq 70^{\circ}\text{C}$ for the LM11C(L).

Note 5: Refer to RETS11X for LM11 military specifications.

Application Hints

When working with circuitry capable of resolving picoampere level signals, leakage currents in circuitry external to the op amp can significantly degrade performance. High quality insulation is a must (Kel-F and Teflon rate high). Proper cleaning of all insulating surfaces to remove fluxes and other residues is also required. This includes the IC package as well as sockets and printed circuit boards. When operating in high humidity environments or near 0°C, some form of surface coating may be necessary to provide a moisture barrier.

The effects of board leakage can be minimized by encircling the input circuitry with a conductive guard ring operated at a potential close to that of the inputs. For critical applications, dual-in-line packages are available that include input guard pins.

Electrostatic shielding of high impedance circuitry is advisable.

Error voltages can also be generated in the external circuitry. Thermocouples formed between dissimilar metals can cause hundreds of microvolts of error in the presence of temperature gradients. The most troublesome thermocouples are the junction of the IC package and the printed circuit board (35 μ V/°C for copper-kovar) and internal resis-

tor connections. Problems can be avoided by keeping low level circuitry away from heat generating elements. Mounting the IC directly to the PC board while keeping package leads short and the input leads close together can also help.

With the LM11 there is a temptation to remove the bias-current-compensation resistor normally used on the noninverting input of a summing amplifier. Direct connection of the inputs to ground or a low-impedance voltage source is not recommended with supply voltages greater than about 3V. The potential problem involves reversal of one supply which can cause excessive current in the second supply. Destruction of the IC could result if the output current of the second supply is not limited to about 100 mA or if there is much more than 1 μ F bypass on the supply buss.

Just disconnecting one supply will generally involve reversal because of loading to the other supply both within the IC and in external circuitry. Although difficulties can be largely avoided by installing clamp diodes across the supply lines on every PC board, a conservative design would include enough resistance in the input lead to limit current to 10 mA if the input lead is pulled to either supply by internal currents. This precaution is by no means limited to the LM11.

Application Hints (Continued)

Input Guarding

Input guarding can drastically reduce surface leakage. Layout for metal can is shown here. Guarding both sides of board is required. Bulk leakage reduction is less and depends on guard ring width.

TL/H/5653-4

Guard ring is connected to low impedance point at same potential as sensitive input leads. Connections for various op amp configurations are here.

TL/H/5653-7

Input Protection

Current is limited by R2 even when input is connected to voltage source outside common mode range. If one supply reverses, current is controlled by R1. These resistors do not affect normal operation.

TL/H/5653-5

Input resistor controls current when input exceeds supply voltages, when power for op amp is turned off or when output is shorted.

TL/H/5653-6

Balancing And Over-Compensation

Over-compensation will improve stability with capacitive loading (see curves). Offset voltage adjustment range is determined by balance potentiometer resistance as indicated in the table.

† See stability with over-compensation curve

TL/H/5653-8

min. adj range	R
± 4 mV	100 kΩ
± 2	10k
± 0.8	3k
± 0.4	1k

Application Hints (Continued)

Resistance Multiplication

Equivalent feedback resistance is 10 GΩ, but only standard resistors are used. Even though the offset voltage is multiplied by 100, output offset is actually reduced because error is dependent on offset current rather than bias current. Voltage on summing junction is less than 5 mV.

TL/H/5653-9

Follower input resistance is 1 GΩ. With the input open, offset voltage is multiplied by 100, but the added error is not great because the op amp offset is low.

TL/H/5653-11

This circuit multiplies RC time constant to 1000 seconds and provides low output impedance.

TL/H/5653-13

$$\pi = \frac{R_1 C}{R_3 (R_2 + R_3)}$$

$$\Delta V_{OUT} = \frac{R_1 + R_3}{R_3} (I_b R_2 + V_{OS})$$

A high-input-impedance ac amplifier for a piezoelectric transducer. Input resistance of 880 MΩ and gain of 10 is obtained.

TL/H/5653-10

$$R_{IN} = R_1 \left(1 + \frac{R_2}{R_3} \right) \quad A_V = \frac{R_2 + R_3 + R_4}{R_2 + R_3}$$

Cable Bootstrapping

Bootstrapping input shield for a follower reduces cable capacitance, leakage and spurious voltages from cable flexing. Instability can be avoided with small capacitor on input.

TL/H/5653-12

With summing amplifier, summing node is at virtual ground so input shield is best grounded. Small feedback capacitor insures stability.

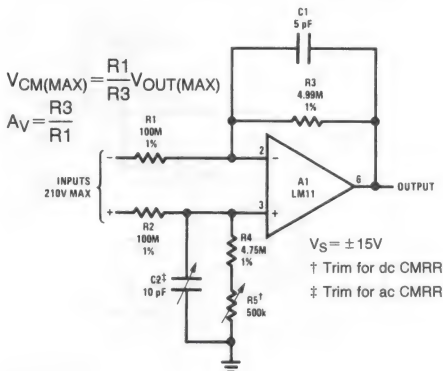

TL/H/5653-14

Application Hints (Continued)

Differential Amplifiers

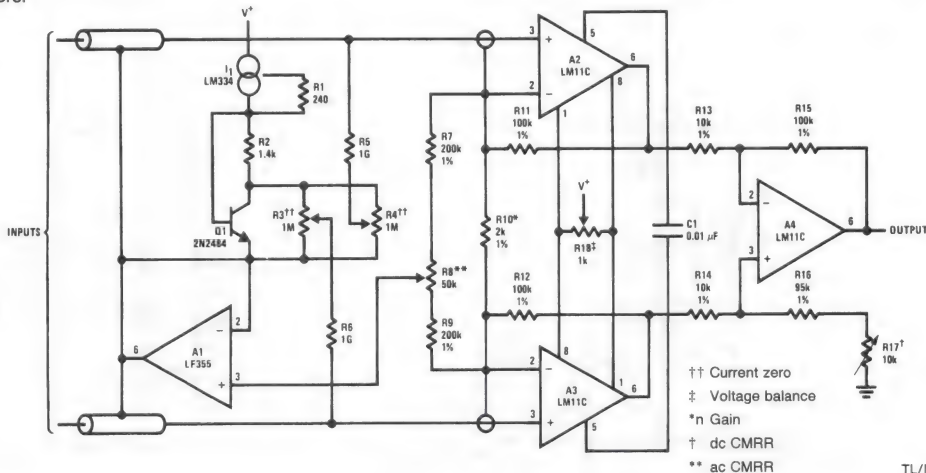

This differential amplifier handles high input voltages. Resistor mismatches and stray capacitors should be balanced out for best common-mode rejection.

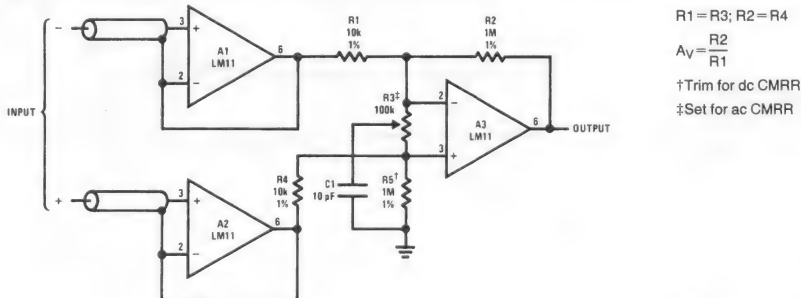

Two op-amp instrumentation amplifier has poor ac common mode rejection. This can be improved at the expense of differential bandwidth with C2.

High gain differential instrumentation amplifier includes input guarding, cable bootstrapping and bias current compensation. Differential bandwidth is reduced by C1 which also makes common-mode rejection less dependent on matching of input amplifiers.

For moderate-gain instrumentation amplifiers, input amplifiers can be connected as followers. This simplifies circuitry, but A3 must also have low drift.

Application Hints (Continued)

Bias Current Compensation

Precise bias current compensation for use with unregulated supplies. Reference voltage is available for other circuitry.

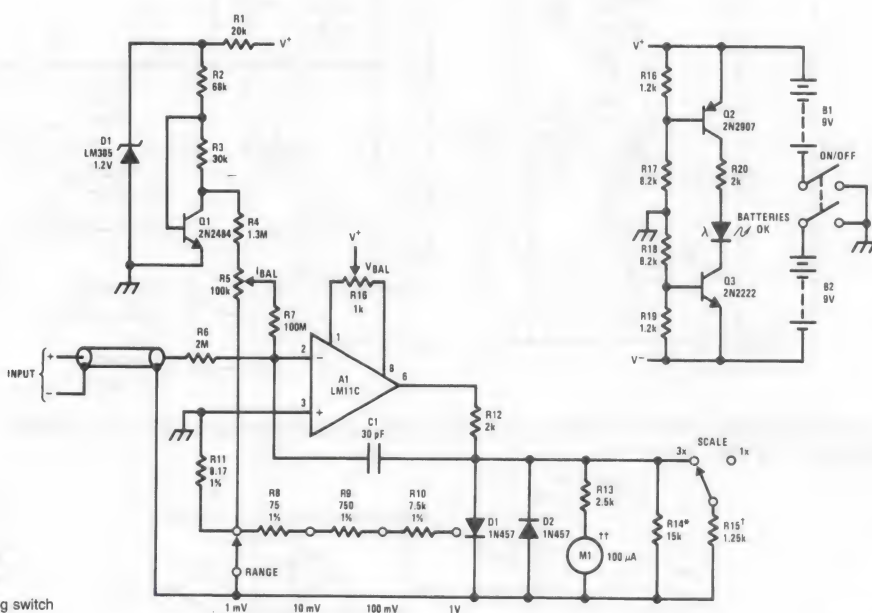

This circuit shows how bias current compensation can be used on a voltage follower.

TL/H/5653-18

Voltmeter

High input impedance millivoltmeter. Input current is proportional to input voltage, about 10 pA at full scale. Reference could be used to make direct reading linear ohmmeter.

* 1 × scale calibrate

† 3× scale calibrate

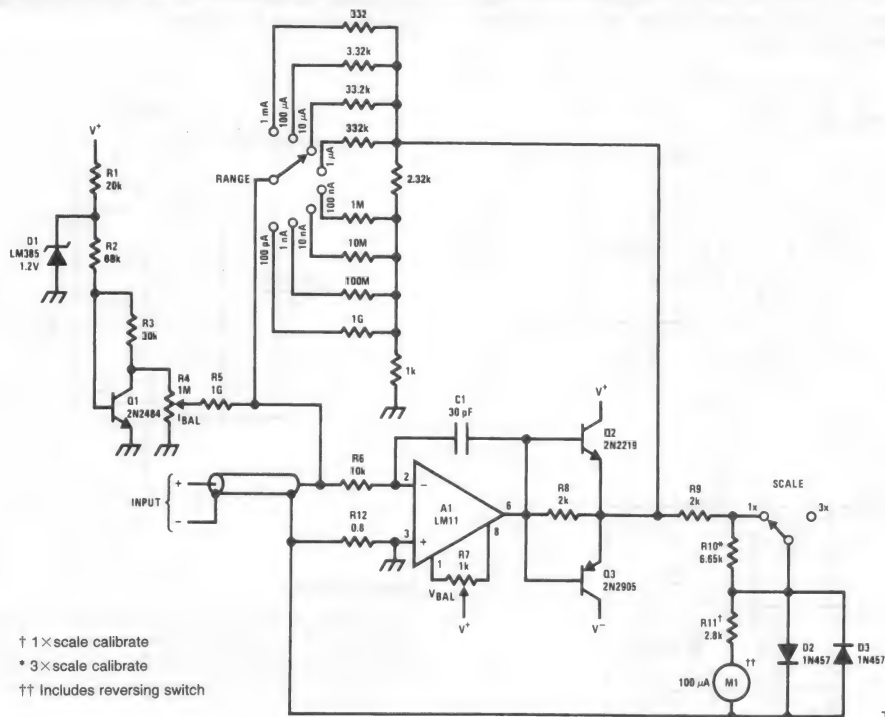

†† Includes reversing switch

TL/H/5653-19

Application Hints (Continued)

Ammeter

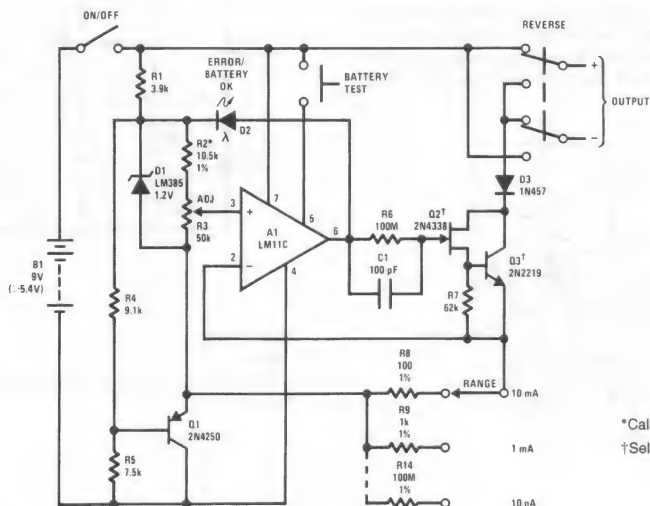

Current meter ranges from 100 pA to 3 mA full scale. Voltage across input is 100 μ V at lower ranges rising to 3 mV at 3 mA. Buffers on op amp are to remove ambiguity with high-current overload. Output can also drive DVM or DPM.

TL/H/5653-20

Current Source

Precision current source has 10 μ A to 10 mA ranges with output compliance of 30V to -5 V. Output current is fully adjustable on each range with a calibrated, ten-turn potentiometer. Error light indicates saturation.

TL/H/5653-21

Application Hints (Continued)

Fast Amplifiers

These inverters have bias current and offset voltage of LM11 along with speed of the FET op amps. Open loop gain is about 140 dB and settling time to 1 mV about 8 μ s. Overload-recovery delay can be eliminated by direct coupling the FET amplifier to summing node.

TL/H/5653-22

This 100× amplifier has small and large signal bandwidth of 1 MHz. The LM11 greatly reduces offset voltage, bias current and gain error. Eliminating long recovery delay for greater than 100% overload requires direct coupling of A2 to input.

TL/H/5653-24

Follower has 10 μ S setting to 1 mV, but signal repetition frequency should not exceed 10 kHz if the FET amplifier is ac coupled to input. The circuit does not behave well if common-mode range is exceeded.

TL/H/5653-23

Heater Control

Proportional control crystal oven heater uses lead/lag compensation for fast settling. Time constant is changed with R4 and compensating resistor R5. If Q2 is inside oven, a regulated supply is recommended for 0.1°C control.

TL/H/5653-25

* Solid tantalum

† Mylar

‡ Close thermal coupling between sensor and oven shell is recommended.

Application Hints (Continued)

Leakage Isolation

Switch leakage in this sample and hold does not reach storage capacitor.

*Polystyrene or Teflon
†Required if protected-gate switch is used

TL/H/5653-26

A peak detector designed for extended hold. Leakage currents of peak-detecting diodes and reset switch are absorbed before reaching storage capacitor.

300 μ S min single pulse
200 μ S min repetitive pulse
300 Hz max sine wave error < 5 mV

†Required if Q1 has gate-protection diode
*Polystyrene or Teflon

TL/H/5653-27

Reset is provided for this integrator and switch leakage is isolated from the summing junction. Greater precision can be provided if bias-current compensation is included.

*Polystyrene or Teflon
†Required if protected-gate switch is used

Standard-Cell Buffer

Battery powered buffer amplifier for standard cell has negligible loading and disconnects cell for low supply voltage or overload on output. Indicator diode extinguishes as disconnect circuitry is activated.

TL/H/5653-28

*Cannot have gate protection diode; $V_{TH} > V_{OUT}$

Application Hints (Continued)

Logarithmic Amplifiers

Unusual frequency compensation gives this logarithmic converter a 100 μ s, time constant from 1 mA down to 100 μ A, increasing from 200 μ s to 200 ms from 10 nA to 10 pA. Optional bias current compensation can give 10 pA resolution from -55°C to 100°C . Scale factor is 1V/decade and temperature compensated.

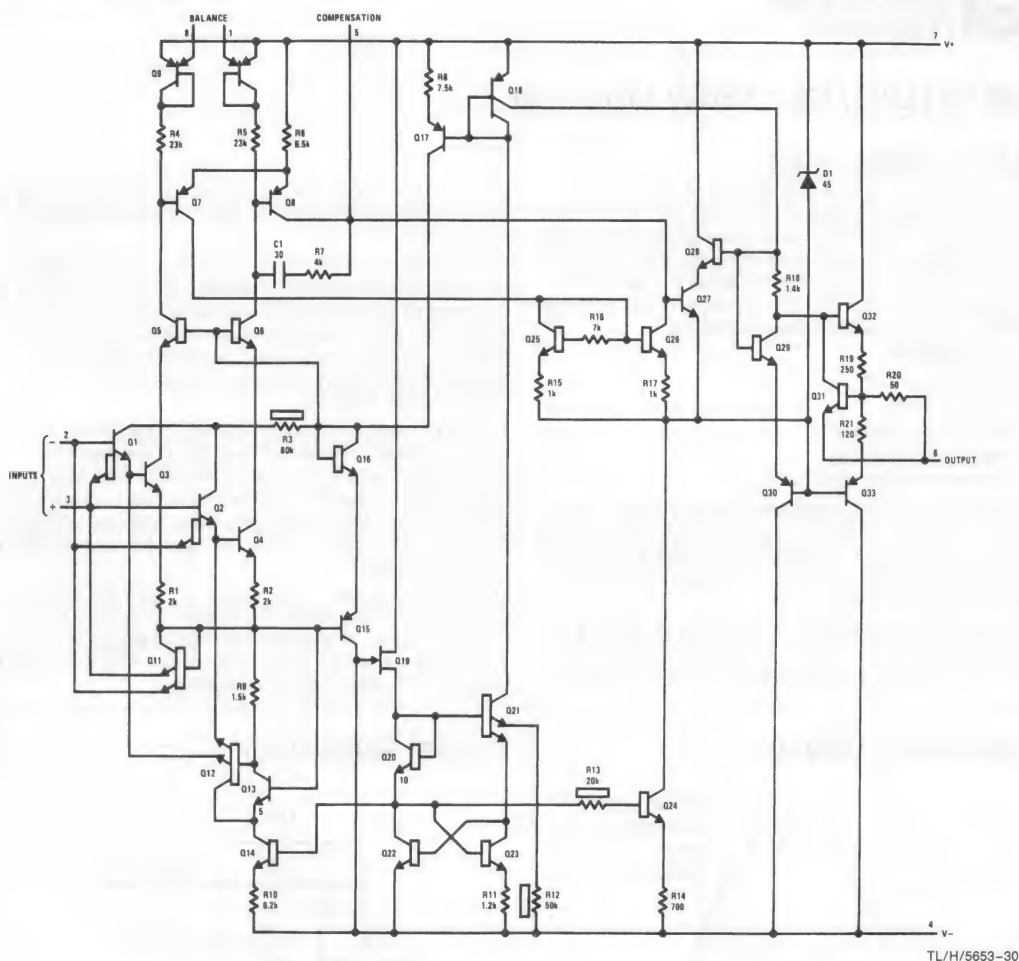

- Set R11 for $V_{OUT}=0$ at $I_{IN}=100$ nA
 - Set R8 for $V_{OUT}=3\text{V}$ at $I_{IN}=100$ μ A
 - Set R3 for $V_{OUT}=-4\text{V}$ at $I_{IN}=10$ pA
- † 3500 ppm/ $^{\circ}\text{C}$. Type Q81 available from Tel Labs Inc., Londonderry, N.H.

Light meter has eight-decade range. Bias current compensation can give input current resolution of better than ± 2 pA over 15°C to 55°C .

- ‡ $V_1=0$ @ $I_{IN}=100$ nA
 † $V_1=-0.24\text{V}$ @ $I_{IN}=10$ pA
 * $M1=0$ @ $I_{IN}=10$ pA
 ** $M1=f_S$ @ $I_{IN}=1$ mA

Schematic Diagram

Definition of Terms

Input offset voltage: That voltage which must be applied between the input terminals to bias the unloaded output in the linear region.

Input offset current: The difference in the currents at the input terminals when the output is unloaded in the linear region.

Input bias current: The absolute value of the average of the two input currents.

Input resistance: The ratio of the change in input voltage to the change in input current on either input with the other grounded.

Large signal voltage gain: The ratio of the specified output voltage swing to the change in differential input voltage required to produce it.

Common-mode rejection: The ratio of the input voltage range to the change in offset voltage between the extremes.

Temperature drift: The change of a parameter measured at 25°C and either temperature extreme divided by the temperature change.

Power Supply Rejection Ratio: The ratio of the specified supply-voltage change (either or both supplies) to the change in offset voltage between the extremes.

Supply current: The current required from the power source to operate the amplifier with the output unloaded and operating in the linear range.

LM12 (L/C/CL) 150W Op Amp

General Description

The LM12 is a power op amp capable of driving $\pm 35V$ at $\pm 10A$ while operating from $\pm 40V$ supplies. The monolithic IC can deliver 150W of sine wave power into a 4Ω load with 0.01% distortion. Power bandwidth is 60 kHz. Further, a peak dissipation capability of 800W allows it to handle reactive loads such as transducers, actuators or small motors without derating. Important features include:

- input protection
- controlled turn on
- thermal limiting
- overvoltage shutdown
- output-current limiting
- dynamic safe-area protection

The IC delivers $\pm 10A$ output current at any output voltage yet is completely protected against overloads, including shorts to the supplies. The dynamic safe-area protection is provided by instantaneous peak-temperature limiting within the power transistor array.

The turn-on characteristics are controlled by keeping the output open-circuited until the total supply voltage reaches 14V. The output is also opened as the case temperature

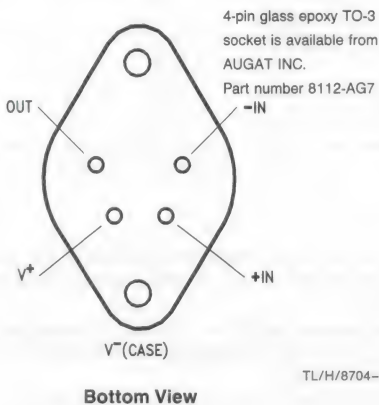

exceeds $150^\circ C$ or as the supply voltage approaches the BV_{CEO} of the output transistors. The IC withstands overvoltages to 100V.

This monolithic op amp is compensated for unity-gain feedback, with a small-signal bandwidth of 700 kHz. Slew rate is $9V/\mu s$, even as a follower. Distortion and capacitive-load stability rival that of the best designs using complementary output transistors. Further, the IC withstands large differential input voltages and is well behaved should the common-mode range be exceeded.

The LM12 establishes that monolithic ICs can deliver considerable output power without resorting to complex switching schemes. Devices can be paralleled or bridged for even greater output capability. Applications include operational power supplies, high-voltage regulators, high-quality audio amplifiers, tape-head positioners, x-y plotters or other servo-control systems.

The LM12 is supplied in a four-lead, TO-3 package with V^- on the case. A gold-eutectic die-attach to a molybdenum interface is used to avoid thermal fatigue problems. Two voltage grades are available; both are specified for either military or commercial temperature range.

output-current limit	$t_{ON} = 10$ ms, $V_{DISS} = 10V$	13	16	16	A (max)
	$t_{ON} = 100$ ms, $V_{DISS} = 58V$	1.5	1.0/ 0.6	0.9/ 0.6	A (min)
		1.5	1.7	1.7	A (max)
	LM12/LM12C $t_{ON} = 100$ ms, $V_{DISS} = 78V$	0.7	0.6/ 0.4	0.5/ 0.35	A (min)
power dissipation rating	$t_{ON} = 100$ mS, $V_{DISS} = 20V$	100	90/ 40	80/ 55	W (min)
	$V_{DISS} = 58V$	80	58/ 35	52/ 35	W (min)
dc thermal resistance	(Note 4) $V_{DISS} = 20V$	2.3	2.6	2.9	°C/W (max)
	$V_{DISS} = 58V$	2.7	4.0	4.5	°C/W (max)
ac thermal resistance	(Note 4)	1.6	1.9	2.1	°C/W (max)
supply current	$V_{OUT} = 0$, $I_{OUT} = 0$	60	80/ 90	120/ 140	mA (max)

Note 1. Neither input should exceed the supply voltage by more than 50 volts nor should the voltage between one input and any other terminal exceed 80 volts for the LM12/LM12C or 60 volts for the LM12L/LM12CL.

Note 2. Operating junction temperature is internally limited near 225°C within the power transistor and 160°C for the control circuitry.

Note 3. The supply voltage is $\pm 40V$ ($V_{MAX} = 80V$) for the LM12/LM12C and $\pm 30V$ ($V_{MAX} = 60V$) for the LM12L/LM12CL, unless otherwise specified. The voltage across the conducting output transistor (supply to output) is V_{PDISS} and internal power dissipation is P_{DISS} . Temperature range is $-55^\circ C \leq T_C \leq 125^\circ C$ for the LM12/LM12L and $0^\circ C \leq T_C \leq 70^\circ C$ for LM12C/LM12CL, where T_C is the case temperature. Standard typeface indicates limits at 25°C while **boldface type** refers to limits or special conditions over full temperature range. With no heat sink, the package will heat at a rate of 35°C/sec per 100W of internal dissipation.

Note 4. This thermal resistance is based upon a peak temperature of 200°C in the center of the power transistor and a case temperature of 25°C measured at the center of the package bottom. The maximum junction temperature of the control circuitry can be estimated based upon a dc thermal resistance of 0.9°C/W or an ac thermal resistance of 0.6°C/W for any operating voltage.

Although the output and supply leads are resistant to electrostatic discharges from handling, the input leads are not. The part should be treated accordingly.

LM12

TL/H/8704-5

Application Information

general

Twenty five years ago the operational amplifier was a specialized design tool used primarily for analog computation. However, the availability of low cost IC op amps in the late 1960's prompted their use in rather mundane applications, replacing a few discrete components. Once a few basic principles are mastered, op amps can be used to give exceptionally good results in a wide range of applications while minimizing both cost and design effort.

The availability of a monolithic power op amp now promises to extend these advantages to high-power designs. Some conventional applications are given here to illustrate op amp design principles as they relate to power circuitry. The inevitable fall in prices, as the economies of volume production are realized, will prompt their use in applications that might now seem trivial. Replacing single power transistors with an op amp will become economical because of improved performance, simplification of attendant circuitry, vastly improved fault protection, greater reliability and the reduction of design time.

Power op amps introduce new factors into the design equation. With current transients above 10A, both the inductance and resistance of wire interconnects become important in a number of ways. Further, power ratings are a crucial factor in determining performance. But the power capability of the IC cannot be realized unless it is properly mounted to an adequate heat sink. Thus, thermal design is of major importance with power op amps.

This application summary starts off by identifying the origin of strange problems observed while using the LM12 in a wide variety of designs with all sorts of fault conditions. A few simple precautions will eliminate these problems. **One would do well to read the section on supply bypassing, lead inductance, output clamp diodes, ground loops and reactive loading before doing any experimentation. Should there be problems with erratic operation, blow-outs, excessive distortion or oscillation, another look at these sections is in order.**

The management and protection circuitry can also affect operation. Should the total supply voltage exceed ratings or drop below 15V, the op amp shuts off completely. Case temperatures above 150°C also cause shut down until the temperature drops to 145°C. This may take several seconds, depending on the thermal system. Activation of the dynamic safe-area protection causes both the main feedback loop to lose control and a reduction in output power, with possible oscillations. In ac applications, the dynamic protection will cause waveform distortion. Since the LM12 is well protected against thermal overloads, the suggestions for determining power dissipation and heat sink requirements are presented last.

supply bypassing

All op amps should have their supply leads bypassed with low-inductance capacitors having short leads and located close to the package terminals to avoid spurious oscillation problems. Power op amps require larger bypass capacitors. The LM12 is stable with good-quality electrolytic bypass capacitors greater than 20 μ F. Other considerations may require larger capacitors.

The current in the supply leads is a rectified component of the load current. If adequate bypassing is not provided, this distorted signal can be fed back into internal circuitry. Low distortion at high frequencies requires that the supplies be bypassed with 470 μ F or more, at the package terminals.

lead inductance

With ordinary op amps, lead-inductance problems are usually restricted to supply bypassing. Power op amps are also sensitive to inductance in the output lead, particularly with heavy capacitive loading. Feedback to the input should be taken directly from the output terminal, minimizing common inductance with the load. Sensing to a remote load must be accompanied by a high-frequency feedback path directly from the output terminal. Lead inductance can also cause voltage surges on the supplies. With long leads to the power source, energy stored in the lead inductance when the output is shorted can be dumped back into the supply bypass capacitors when the short is removed. The magnitude of this transient is reduced by increasing the size of the bypass capacitor near the IC. With 20 μ F local bypass, these voltage surges are important only if the lead length exceeds a couple feet ($> 1 \mu$ H lead inductance). Twisting together the supply and ground leads minimizes the effect.

ground loops

With fast, high-current circuitry, all sorts of problems can arise from improper grounding. In general, difficulties can be avoided by returning all grounds separately to a common point. Sometimes this is impractical. When compromising, special attention should be paid to the ground returns for the supply bypasses, load and input signal. Ground planes also help to provide proper grounding.

Many problems unrelated to system performance can be traced to the grounding of line-operated test equipment used for system checkout. Hidden paths are particularly difficult to sort out when several pieces of test equipment are used but can be minimized by using current probes or the new isolated oscilloscope pre-amplifiers. Eliminating any direct ground connection between the signal generator and the oscilloscope synchronization input solves one common problem.

output clamp diodes

When a push-pull amplifier goes into power limit while driving an inductive load, the stored energy in the load inductance can drive the output outside the supplies. Although the LM12 has internal clamp diodes that can handle several amperes for a few milliseconds, extreme conditions can cause destruction of the IC. The internal clamp diodes are imperfect in that about half the clamp current flows into the supply to which the output is clamped while the other half flows across the supplies. Therefore, the use of external diodes to clamp the output to the power supplies is strongly recommended. This is particularly important with higher supply voltages.

Experience has demonstrated that hard-wire shorting the output to the supplies can induce random failures if these external clamp diodes are not used and the supply voltages are above ± 20 V. Therefore it is prudent to use output-

clamp diodes even when the load is not particularly inductive. This also applies to experimental setups in that blow-outs have been observed when diodes were not used. In packaged equipment, it may be possible to eliminate these diodes, providing that fault conditions can be controlled.

TL/H/8704-6

Heat sinking of the clamp diodes is usually unimportant in that they only clamp current transients. Forward drop with 15A fault transients is of greater concern. Usually, these transients die out rapidly. The clamp to the negative supply can have somewhat reduced effectiveness under worst case conditions should the forward drop exceed 1.0V. Mounting this diode to the power op amp heat sink improves the situation. Although the need has only been demonstrated with some motor loads, including a third diode (D3 above) will eliminate any concern about the clamp diodes. This diode, however, must be capable of dissipating continuous power as determined by the negative supply current of the op amp.

reactive loading

The LM12 is normally stable with resistive, inductive or smaller capacitive loads. Larger capacitive loads interact with the open-loop output resistance (about 1 Ω) to reduce the phase margin of the feedback loop, ultimately causing oscillation. The critical capacitance depends upon the feedback applied around the amplifier; a unity-gain follower can handle about 0.01 μ F, while more than 1 μ F does not cause problems if the loop gain is ten. With loop gains greater than unity, a speedup capacitor across the feedback resistor will aid stability. In all cases, the op amp will behave predictably only if the supplies are properly bypassed, ground loops are controlled and high-frequency feedback is derived directly from the output terminal, as recommended earlier.

So-called capacitive loads are not always capacitive. A high-Q capacitor in combination with long leads can present a series-resonant load to the op amp. In practice, this is not usually a problem; but the situation should be kept in mind.

TL/H/8704-7

Large capacitive loads (including series-resonant) can be accommodated by isolating the feedback amplifier from the load as shown above. The inductor gives low output impedance at lower frequencies while providing an isolating impedance at high frequencies. The resistor kills the Q of series resonant circuits formed by capacitive loads. A low inductance, carbon-composition resistor is recommended. Optimum values of L and R depend upon the feedback gain

and expected nature of the load, but are not critical. A 4 μ H inductor is obtained with 14 turns of number 18 wire, close spaced, around a one-inch-diameter form.

TL/H/8704-8

The LM12 can be made stable for all loads with a large capacitor on the output, as shown above. This compensation gives the lowest possible closed-loop output impedance at high frequencies and the best load-transient response. It is appropriate for such applications as voltage regulators.

A feedback capacitor, C_1 , is connected directly to the output pin of the IC. The output capacitor, C_2 , is connected at the output terminal with short leads. Single-point grounding to avoid dc and ac ground loops is advised.

The impedance, Z_1 , is the wire connecting the op amp output to the load capacitor. About 3-inches of number-18 wire (70 nH) gives good stability and 18-inches (400 nH) begins to degrade load-transient response. The minimum load capacitance is 47 μ F, if a solid-tantalum capacitor with an equivalent series resistance (ESR) of 0.1 Ω is used. Electrolytic capacitors work as well, although capacitance may have to be increased to 200 μ F to bring ESR below 0.1 Ω .

Loop stability is not the only concern when op amps are operated with reactive loads. With time-varying signals, power dissipation can also increase markedly. This is particularly true with the combination of capacitive loads and high-frequency excitation.

input compensation

The LM12 is prone to low-amplitude oscillation bursts coming out of saturation if the high-frequency loop gain is near unity. The voltage follower connection is most susceptible. This glitching can be eliminated at the expense of small-signal bandwidth using input compensation. Input compensation can also be used in combination with LR load isolation to improve capacitive load stability.

TL/H/8704-9

An example of a voltage follower with input compensation is shown here. The R_2C_2 combination across the input works with R_1 to reduce feedback at high frequencies without greatly affecting response below 100 kHz. A lead capacitor, C_1 , improves phase margin at the unity-gain crossover frequency. Proper operation requires that the output impedance of the circuitry driving the follower be well under 1 k Ω at frequencies up to a few hundred kilohertz.

TL/H/8704-10

Extending input compensation to the integrator connection is shown here. Both the follower and this integrator will handle 1 μ F capacitive loading without LR output isolation.

current drive

TL/H/8704-11

This circuit provides an output current proportional to the input voltage. Current drive is sometimes preferred for servo motors because it aids in stabilizing the servo loop by reducing phase lag caused by motor inductance. In applications requiring high output resistance, such as operational power supplies running in the current mode, matching of the feedback resistors to 0.01% is required. Alternately, an adjustable resistor can be used for trimming.

parallel operation

TL/H/8704-12

Output drive beyond the capability of one power amplifier can be provided as shown here. The power op amps are wired as followers and connected in parallel with the outputs coupled through equalization resistors. A standard, high-voltage op amp is used to provide voltage gain. Overall feedback compensates for the voltage dropped across the equalization resistors.

With parallel operation, there may be an increase in unloaded supply current related to the offset voltage across the

equalization resistors. More output buffers, with individual equalization resistors, may be added to meet even higher drive requirements.

TL/H/8704-13

This connection allows increased output capability without requiring a separate control amplifier. The output buffer, A2, provides load current through R5 equal to that supplied by the main amplifier, A1, through R4. Again, more output buffers can be added.

Current sharing among paralleled amplifiers can be affected by gain error as the power-bandwidth limit is approached. In the first circuit, the operating current increase will depend upon the matching of high-frequency characteristics. In the second circuit, however, the entire input error of A2 appears across R4 and R5. The supply current increase can cause power limiting to be activated as the slew limit is approached. This will not damage the LM12. It can be avoided in both cases by connecting A1 as an inverting amplifier and restricting bandwidth with C1.

single-supply operation

TL/H/8704-14

Although op amps are usually operated from dual supplies, single-supply operation is practical. This bridge amplifier supplies bi-directional current drive to a servo motor while operating from a single positive supply. The output is easily converted to voltage drive by shorting R6 and connecting R7 to the output of A2, rather than A1.

Either input may be grounded, with bi-directional drive provided to the other. It is also possible to connect one input to a positive reference, with the input signal varying about this voltage. If the reference voltage is above 5V, R2 and R3 are not required.

high voltage amplifiers

TL/H/8704-15

The voltage swing delivered to the load can be doubled by using the bridge connection shown here. Output clamping to the supplies can be provided by using a bridge-rectifier assembly.

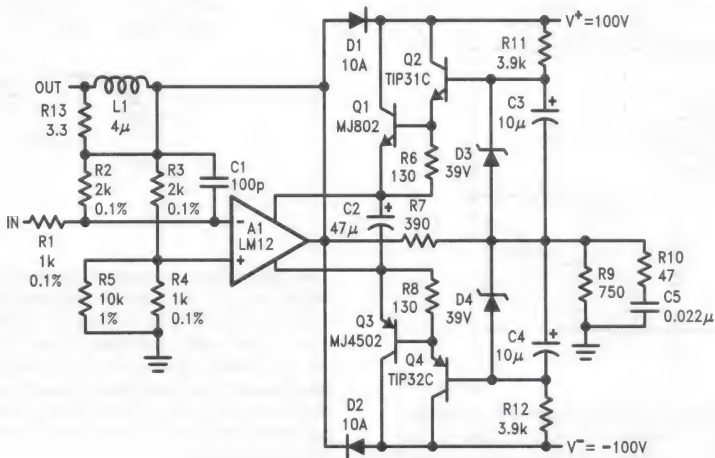

TL/H/8704-16

One limitation of the standard bridge connection is that the load cannot be returned to ground. This can be circumvented by operating the bridge with floating supplies, as shown above. For single-ended drive, either input can be grounded.

TL/H/8704-17

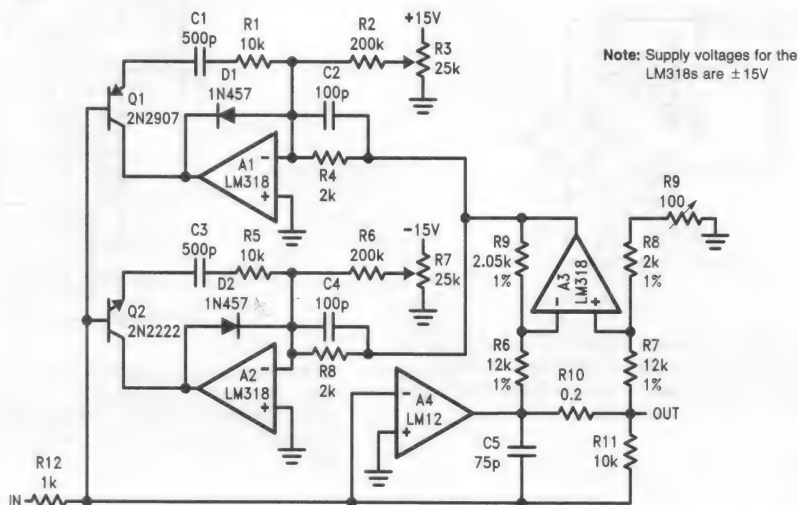

This circuit shows how two amplifiers can be cascaded to double output swing. The advantage over the bridge is that the output can be increased with any number of stages, although separate supplies are required for each.

TL/H/8704-18

Discrete transistors can be used to increase output drive to $\pm 90\text{V}$ at $\pm 10\text{A}$ as shown above. With proper thermal design, the IC will provide safe-area protection for the external transistors. Voltage gain is about thirty.

operational power supply

TL/H/8704-19

External current limit can be provided for a power op amp as shown above. The positive and negative current limits can be set precisely and independently. Fast response is assured by D_1 and D_2 . Adjustment range can be set down to zero with potentiometers R_3 and R_7 . Alternately, the limit can be programmed from a voltage supplied to R_2 and R_6 . This is the set up required for an operational power supply or voltage-programmable power source.

servo amplifiers

When making servo systems with a power op amp, there is a temptation to use it for frequency shaping to stabilize the servo loop. Sometimes this works; other times there are better ways; and occasionally it just doesn't fly. Usually it's a matter of how quickly and to what accuracy the servo must stabilize.

TL/H/8704-20

This motor/tachometer servo gives an output speed proportional to input voltage. A low-level op amp is used for frequency shaping while the power op amp provides current drive to the motor. Current drive eliminates loop phase shift due to motor inductance and makes high-performance servos easier to stabilize.

TL/H/8704-21

This position servo uses an op amp to develop the rate signal electrically instead of using a tachometer. In high-performance servos, rate signals must be developed with large error signals well beyond saturation of the motor drive. Using a separate op amp with a feedback clamp allows the rate signal to be developed properly with position errors more than an order of magnitude beyond the loop-saturation level as long as the photodiode sensors are positioned with this in mind.

voltage regulators

TL/H/8704-22

An op amp can be used as a positive or negative regulator. Unlike most regulators, it can sink current to absorb energy dumped back into the output. This positive regulator has a 0–70V output range.

TL/H/8704-23

Dual supplies are not required to use an op amp as a voltage regulator if zero output is not required. This 4V to 70V regulator operates from a single supply. Should the op amp not be able to absorb enough energy to control an overvoltage condition, a SCR will crowbar the output.

remote sensing

TL/H/8704-24

Remote sensing as shown above allows the op amp to correct for dc drops in cables connecting the load. Even so, cable drop will affect transient response. Degradation can be minimized by using twisted, heavy-gauge wires on the output line. Normally, common and one input are connected together at the sending end.

audio amplifiers

TL/H/8704-25

A power amplifier suitable for use in high-quality audio equipment is shown above. Harmonic distortion is about 0.01-percent. Intermodulation distortion (60 Hz/7 kHz, 4:1) measured 0.015-percent. Transient response and saturation recovery are clean, and the 9 V/μs slew rate of the LM12 virtually eliminates transient intermodulation distortion. Using separate amplifiers to drive low- and high-frequency speakers gets rid of high-level crossover networks and attenuators. Further, it prevents clipping on the low-frequency channel from distorting the high frequencies.

determining maximum dissipation

It is a simple matter to establish power requirements for an op amp driving a resistive load at frequencies well below 10 Hz. Maximum dissipation occurs when the output is at one-half the supply voltage with high-line conditions. The individual output transistors must be rated to handle this power continuously at the maximum expected case temperature. The power rating is limited by the maximum junction temperature as determined by

$$T_J = T_C + P_{DISS} \theta_{JC}$$

where T_C is the case temperature as measured at the center of the package bottom, P_{DISS} is the maximum power dissipation and θ_{JC} is the thermal resistance at the operating voltage of the output transistor. Recommended maximum junction temperatures are 200°C within the power transistor and 150°C for the control circuitry.

If there is ripple on the supply bus, it is valid to use the average value in worst-case calculations as long as the peak rating of the power transistor is not exceeded at the ripple peak. With 120 Hz ripple, this is 1.5 times the continuous power rating.

Dissipation requirements are not so easily established with time varying output signals, especially with reactive loads. Both peak and continuous dissipation ratings must be taken into account, and these depend on the signal waveform as well as load characteristics.

With a sine wave output, analysis is fairly straightforward. With supply voltages of $\pm V_S$, the maximum average power dissipation of both output transistors is

$$P_{MAX} = \frac{2V_S^2}{\pi^2 Z_L \cos \theta}, \quad \theta < 40^\circ;$$

and

$$P_{MAX} = \frac{V_S^2}{2Z_L} \left[\frac{4}{\pi} - \cos \theta \right], \quad \theta \geq 40^\circ,$$

where Z_L is the magnitude of the load impedance and θ its phase angle. Maximum average dissipation occurs below maximum output swing for $\theta < 40^\circ$.

TL/H/8704-26

The instantaneous power dissipation over the conducting half cycle of one output transistor is shown here. Power dissipation is near zero on the other half cycle. The output level is that resulting in maximum peak and average dissipation. Plots are given for a resistive and a series RL load. The latter is representative of a 4Ω loudspeaker operating below resonance and would be the worst case condition in most

audio applications. The peak dissipation of each transistor is about four times average. In ac applications, power capability is often limited by the peak ratings of the power transistor.

The pulse thermal resistance of the LM12 is specified for constant power pulse duration. Establishing an exact equivalency between constant-power pulses and those encountered in practice is not easy. However, for sine waves, reasonable estimates can be made at any frequency by assuming a constant power pulse amplitude given by:

$$P_{PK} \approx \frac{V_S^2}{2Z_L} \left[1 - \cos(\phi - \theta) \right],$$

where $\phi = 60^\circ$ and θ is the absolute value of the phase angle of Z_L . Equivalent pulse width is $t_{ON} \approx 0.4\tau$ for $\theta = 0$ and $t_{ON} \approx 0.2\tau$ for $\theta \geq 20^\circ$, where τ is the period of the output waveform.

dissipation driving motors

A motor with a locked rotor looks like an inductance in series with a resistance, for purposes of determining driver dissipation. With slow-response servos, the maximum signal amplitude at frequencies where motor inductance is significant can be so small that motor inductance does not have to be taken into account. If this is the case, the motor can be treated as a simple, resistive load as long as the rotor speed is low enough that the back emf is small by comparison to the supply voltage of the driver transistor.

A permanent-magnet motor can build up a back emf that is equal to the output swing of the op amp driving it. Reversing this motor from full speed requires the output drive transistor to operate, initially, along a loadline based upon the motor resistance and total supply voltage. Worst case, this loadline will have to be within the continuous dissipation rating of the drive transistor; but system dynamics may permit taking advantage of the higher pulse ratings. Motor inductance can cause added stress if system response is fast.

Shunt- and series-wound motors can generate back emf's that are considerably more than the total supply voltage, resulting in even higher peak dissipation than a permanent-magnet motor having the same locked-rotor resistance.

voltage regulator dissipation

The pass transistor dissipation of a voltage regulator is easily determined in the operating mode. Maximum continuous dissipation occurs with high line voltage and maximum load current. As discussed earlier, ripple voltage can be averaged if peak ratings are not exceeded; however, a higher average voltage will be required to insure that the pass transistor does not saturate at the ripple minimum.

Conditions during start-up can be more complex. If the input voltage increases slowly such that the regulator does not go into current limit charging output capacitance, there are no problems. If not, load capacitance and load characteristics must be taken into account. This is also the case if automatic restart is required in recovering from overloads.

Automatic restart or start-up with fast-rising input voltages cannot be guaranteed unless the continuous dissipation rating of the pass transistor is adequate to supply the load current continuously at all voltages below the regulated output voltage. In this regard, the LM12 performs much better than IC regulators using foldback current limit, especially with high-line input voltage above 20V.

power limiting

TL/H/8704-27

Should the power ratings of the LM12 be exceeded, dynamic safe-area protection is activated. Waveforms with this power limiting are shown for the LM12 driving $\pm 36V$ at 40 Hz into 4Ω in series with 24 mH ($\theta = 45^\circ$). With an inductive load, the output clamps to the supplies in power limit, as above. With resistive loads, the output voltage drops in limit. Behavior with more complex RCL loads is between these extremes.

Secondary thermal limit is activated should the case temperature exceed 150°C . This thermal limit shuts down the IC completely (open output) until the case temperature drops to about 145°C . Recovery may take several seconds.

power supplies

Power op amps do not require regulated supplies. However, the worst-case output power is determined by the low-line supply voltage in the ripple trough. The worst-case power dissipation is established by the average supply voltage with high-line conditions. The loss in power output that can be guaranteed is the square of the ratio of these two voltages.

Relatively simple off-line switching power supplies can provide voltage conversion, line isolation and 5-percent regulation while reducing size and weight.

The regulation against ripple and line variations can provide a substantial increase in the power output that can be guaranteed under worst-case conditions. In addition, switching power supplies can convert low-voltage power sources such as automotive batteries up to regulated, dual, high-voltage supplies optimized for powering power op amps.

heat sinking

A semiconductor manufacturer has no control over heat sink design. Temperature rating can only be based upon

case temperature as measured at the center of the package bottom. With power pulses of longer duration than 100 ms, case temperature is almost entirely dependent on heat sink design and the mounting of the IC to the heat sink.

TL/H/8704-28

The design of heat sink is beyond the scope of this work. Convection-cooled heat sinks are available commercially, and their manufacturers should be consulted for ratings. The preceding figure is a rough guide for temperature rise as a function of fin area (both sides) available for convection cooling.

Proper mounting of the IC is required to minimize the thermal drop between the package and the heat sink. The heat sink must also have enough metal under the package to conduct heat from the center of the package bottom to the fins without excessive temperature drop.

A thermal grease such as Wakefield type 120 or Thermalloy Thermacote should be used when mounting the package to the heat sink. Without this compound, thermal resistance will be no better than $0.5^\circ\text{C}/\text{W}$, and probably much worse. With the compound, thermal resistance will be $0.2^\circ\text{C}/\text{W}$ or less, assuming under 0.005 inch combined flatness runout for the package and heat sink. Proper torquing of the mounting bolts is important. Four to six inch-pounds is recommended.

Should it be necessary to isolate V^- from the heat sink, an insulating washer is required. Hard washers like beryllium oxide, anodized aluminum and mica require the use of thermal compound on both faces. Two-mil mica washers are most common, giving about $0.4^\circ\text{C}/\text{W}$ interface resistance with the compound. Silicone-rubber washers are also available. A $0.5^\circ\text{C}/\text{W}$ thermal resistance is claimed without thermal compound. Experience has shown that these rubber washers deteriorate and must be replaced should the IC be dismounted.

Definition of Terms

Input offset voltage: The absolute value of the voltage between the input terminals with the output voltage and current at zero.

Input bias current: The absolute value of the average of the two input currents with the output voltage and current at zero.

Input offset current: The absolute value of the difference in the two input currents with the output voltage and current at zero.

Common-mode rejection: The ratio of the input voltage range to the change in offset voltage between the extremes.

Supply-voltage rejection: The ratio of the specified supply-voltage change to the change in offset voltage between the extremes.

Output saturation threshold: The output swing limit for a specified input drive beyond that required for zero output. It is measured with respect to the supply to which the output is swinging.

Large signal voltage gain: The ratio of the output voltage swing to the differential input voltage required to drive the output from zero to either swing limit. The output swing limit is the supply voltage less a specified quasi-saturation voltage. A pulse of short enough duration to minimize thermal effects is used as a measurement signal.

Thermal gradient feedback: The input offset voltage change caused by thermal gradients generated by heating of the output transistors, but not the package. This effect is delayed by several milliseconds and results in increased gain error below 100 Hz.

Output-current limit: The output current with a fixed output voltage and a large input overdrive. The limiting current drops with time once the protection circuitry is activated.

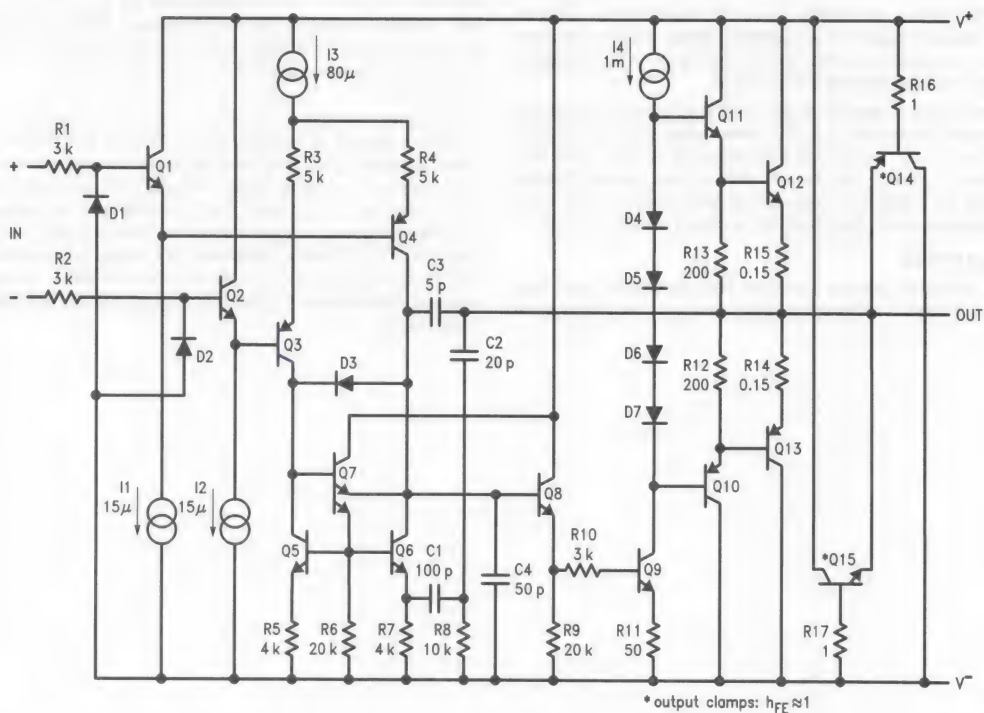

Power dissipation rating: The power that can be dissipated for a specified time interval without activating the protection circuitry. For time intervals in excess of 100 ms, dissipation capability is determined by heat sinking of the IC package rather than by the IC itself.

Thermal resistance: The peak, junction-temperature rise, per unit of internal power dissipation, above the case temperature as measured at the center of the package bottom.

The dc thermal resistance applies when one output transistor is operating continuously. The ac thermal resistance applies with the output transistors conducting alternately at a high enough frequency that the peak capability of neither transistor is exceeded.

Supply current: The current required from the power source to operate the amplifier with the output voltage and current at zero.

Equivalent Schematic (excluding active protection circuitry)

LM101A/LM201A/LM301A Operational Amplifiers

General Description

The LM101A series are general purpose operational amplifiers which feature improved performance over industry standards like the LM709. Advanced processing techniques make possible an order of magnitude reduction in input currents, and a redesign of the biasing circuitry reduces the temperature drift of input current. Improved specifications include:

- Offset voltage 3 mV maximum over temperature (LM101A/LM201A)
- Input current 100 nA maximum over temperature (LM101A/LM201A)
- Offset current 20 nA maximum over temperature (LM101A/LM201A)
- Guaranteed drift characteristics
- Offsets guaranteed over entire common mode and supply voltage ranges
- Slew rate of 10V/ μ s as a summing amplifier

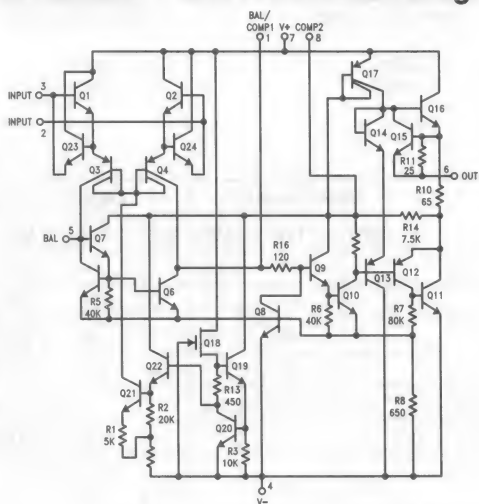

This amplifier offers many features which make its application nearly foolproof: overload protection on the input and

output, no latch-up when the common mode range is exceeded, and freedom from oscillations and compensation with a single 30 pF capacitor. It has advantages over internally compensated amplifiers in that the frequency compensation can be tailored to the particular application. For example, in low frequency circuits it can be overcompensated for increased stability margin. Or the compensation can be optimized to give more than a factor of ten improvement in high frequency performance for most applications.

In addition, the device provides better accuracy and lower noise in high impedance circuitry. The low input currents also make it particularly well suited for long interval integrators or timers, sample and hold circuits and low frequency waveform generators. Further, replacing circuits where matched transistor pairs buffer the inputs of conventional IC op amps, it can give lower offset voltage and a drift at a lower cost.

The LM101A is guaranteed over a temperature range of -55°C to $+125^{\circ}\text{C}$, the LM201A from -25°C to $+85^{\circ}\text{C}$, and the LM301A from 0°C to $+70^{\circ}\text{C}$.

Protecting Against Gross Fault Conditions

Compensating for Stray Input Capacitances or Large Feedback Resistor

Isolating Large Capacitive Loads

Although the LM101A is designed for trouble free operation, experience has indicated that it is wise to observe certain precautions given below to protect the devices from abnormal operating conditions. It might be pointed out that the advice given here is applicable to practically any IC op amp, although the exact reason why may differ with different devices.

When driving either input from a low-impedance source, a limiting resistor should be placed in series with the input lead to limit the peak instantaneous output current of the source to something less than 100 mA. This is especially important when the inputs go outside a piece of equipment where they could accidentally be connected to high voltage sources. Large capacitors on the input (greater than 0.1 μ F) should be treated as a low source impedance and isolated with a resistor. Low impedance sources do not cause a problem unless their output voltage exceeds the supply voltage. However, the supplies go to zero when they are turned off, so the isolation is usually needed.

The output circuitry is protected against damage from shorts to ground. However, when the amplifier output is connected to a test point, it should be isolated by a limiting resistor, as test points frequently get shorted to bad places. Further, when the amplifier drives a load external to the equipment, it is also advisable to use some sort of limiting resistance to preclude mishaps.

Precautions should be taken to insure that the power supplies for the integrated circuit never become reversed—even under transient conditions. With reverse voltages greater than 1V, the IC will conduct excessive current, fusing internal aluminum interconnects. If there is a possibility of this happening, clamp diodes with a high peak current rating should be installed on the supply lines. Reversal of the voltage between V^+ and V^- will always cause a problem, although reversals with respect to ground may also give difficulties in many circuits.

The minimum values given for the frequency compensation capacitor are stable only for source resistances less than 10 k Ω , stray capacitances on the summing junction less than 5 pF and capacitive loads smaller than 100 pF. If any of these conditions are not met, it becomes necessary to overcompensate the amplifier with a larger compensation capacitor. Alternately, lead capacitors can be used in the feedback network to negate the effect of stray capacitance and large feedback resistors or an RC network can be added to isolate capacitive loads.

Although the LM101A is relatively unaffected by supply bypassing, this cannot be ignored altogether. Generally it is necessary to bypass the supplies to ground at least once on every circuit card, and more bypass points may be required if more than five amplifiers are used. When feed-forward compensation is employed, however, it is advisable to bypass the supply leads of each amplifier with low inductance capacitors because of the higher frequencies involved.

LM107/LM207/LM307 Operational Amplifiers

General Description

The LM107 series are complete, general purpose operational amplifiers, with the necessary frequency compensation built into the chip. Advanced processing techniques make the input currents a factor of ten lower than industry standards like the 709. Yet, they are a direct, plug-in replacement for the 709, LM101A and 741.

The LM107 series offers the features of the LM101A, which makes its application nearly foolproof. In addition, the device provides better accuracy and lower noise in high impedance circuitry. The low input currents also make it particularly well suited for long interval integrators or timers, sample and hold circuits and low frequency waveform genera-

tors. Further, replacing circuits where matched transistor pairs buffer the inputs of conventional IC op amps, it can give lower offset voltage and drift at a lower cost.

The LM107 is guaranteed over a -55°C to $+125^{\circ}\text{C}$ temperature range, the LM207 from -25°C to $+85^{\circ}\text{C}$ and the LM307 from 0°C to $+70^{\circ}\text{C}$.

Features

- Offset voltage 3 mV maximum over temperature
- Input current 100 nA maximum over temperature
- Offset current 20 nA maximum over temperature
- Guaranteed drift characteristics

LM108/LM208/LM308 Operational Amplifiers

General Description

The LM108 series are precision operational amplifiers having specifications a factor of ten better than FET amplifiers over a -55°C to $+125^{\circ}\text{C}$ temperature range.

The devices operate with supply voltages from $\pm 2\text{V}$ to $\pm 20\text{V}$ and have sufficient supply rejection to use unregulated supplies. Although the circuit is interchangeable with and uses the same compensation as the LM101A, an alternate compensation scheme can be used to make it particularly insensitive to power supply noise and to make supply bypass capacitors unnecessary.

The low current error of the LM108 series makes possible many designs that are not practical with conventional amplifiers. In fact, it operates from $10\text{ M}\Omega$ source resistances,

introducing less error than devices like the 709 with $10\text{ k}\Omega$ sources. Integrators with drifts less than $500\text{ }\mu\text{V}/\text{sec}$ and analog time delays in excess of one hour can be made using capacitors no larger than $1\text{ }\mu\text{F}$.

The LM108 is guaranteed from -55°C to $+125^{\circ}\text{C}$, the LM208 from -25°C to $+85^{\circ}\text{C}$, and the LM308 from 0°C to $+70^{\circ}\text{C}$.

Features

- Maximum input bias current of 3.0 nA over temperature
- Offset current less than 400 pA over temperature
- Supply current of only $300\text{ }\mu\text{A}$, even in saturation
- Guaranteed drift characteristics

Electrical Characteristics (Note 4) (Continued)

Parameter	Condition	LM108/LM208			LM308			Units
		Min	Typ	Max	Min	Typ	Max	
Input Voltage Range	$V_S = \pm 15V$	± 13.5			± 14			V
Common Mode Rejection Ratio		85	100		80	100		dB
Supply Voltage Rejection Ratio		80	96		80	96		dB

Note 1: The maximum junction temperature of the LM108 is 150°C, for the LM208, 100°C and for the LM308, 85°C. For operating at elevated temperatures, devices in the TO-5 package must be derated based on a thermal resistance of 150°C/W, junction to ambient, or 45°C/W, junction to case. The thermal resistance of the dual-in-line package is 100°C/W, junction to ambient.

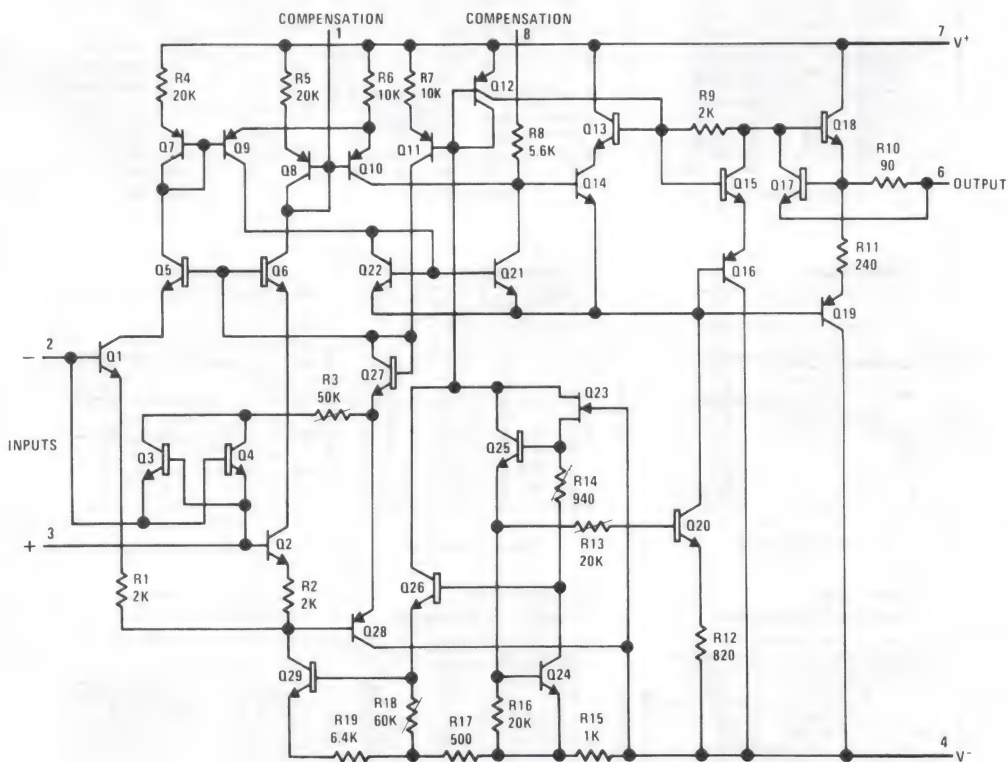

Note 2: The inputs are shunted with back-to-back diodes for overvoltage protection. Therefore, excessive current will flow if a differential input voltage in excess of 1V is applied between the inputs unless some limiting resistance is used.

Note 3: For supply voltages less than $\pm 15V$, the absolute maximum input voltage is equal to the supply voltage.

Note 4: These specifications apply for $\pm 5V \leq V_S \leq +20V$ and $-55^\circ\text{C} \leq T_A \leq +125^\circ\text{C}$, unless otherwise specified. With the LM208, however, all temperature specifications are limited to $-25^\circ\text{C} \leq T_A \leq 85^\circ\text{C}$, and for the LM308 they are limited to $0^\circ\text{C} \leq T_A \leq 70^\circ\text{C}$.

Note 5: Refer to RETS108X for LM108 military specifications.

LM108A/LM208A/LM308A Operational Amplifiers

General Description

The LM108/LM108A series are precision operational amplifiers having specifications about a factor of ten better than FET amplifiers over their operating temperature range. In addition to low input currents, these devices have extremely low offset voltage, making it possible to eliminate offset adjustments, in most cases, and obtain performance approaching chopper stabilized amplifiers.

The devices operate with supply voltages from $\pm 2\text{V}$ to $\pm 18\text{V}$ and have sufficient supply rejection to use unregulated supplies. Although the circuit is interchangeable with and uses the same compensation as the LM101A, an alternate compensation scheme can be used to make it particularly insensitive to power supply noise and to make supply bypass capacitors unnecessary.

The low current error of the LM108A series makes possible many designs that are not practical with conventional amplifiers. In fact, it operates from $10\text{ M}\Omega$ source resistances,

introducing less error than devices like the 709 with $10\text{ k}\Omega$ sources. Integrators with drifts less than $500\text{ }\mu\text{V/sec}$ and analog time delays in excess of one hour can be made using capacitors no larger than $1\text{ }\mu\text{F}$.

The LM208A is identical to the LM108A, except that the LM208A has its performance guaranteed over a -25°C to $+85^\circ\text{C}$ temperature range, instead of -55°C to $+125^\circ\text{C}$. The LM308A devices have slightly-relaxed specifications and performances over a 0°C to $+70^\circ\text{C}$ temperature range.

Features

- Offset voltage guaranteed less than 0.5 mV
- Maximum input bias current of 3.0 nA over temperature
- Offset current less than 400 pA over temperature
- Supply current of only $300\text{ }\mu\text{A}$, even in saturation
- Guaranteed $5\text{ }\mu\text{V}/^\circ\text{C}$ drift

Compensation Circuits

**Bandwidth and slew rate are proportional to $1/C_1$.

**Bandwidth and slew rate are proportional to $1/C_3$.

Supply Voltage Rejection Ratio		96	110		dB

Note 1: The maximum junction temperature of the LM308A is 85°C . For operating at elevated temperatures, devices in the TO-5 package must be derated based on a thermal resistance of $150^{\circ}\text{C}/\text{W}$, junction to ambient, or $45^{\circ}\text{C}/\text{W}$, junction to case. The thermal resistance of the dual-in-line package is $100^{\circ}\text{C}/\text{W}$, junction to ambient.

Note 2: The inputs are shunted with back-to-back diodes for overvoltage protection. Therefore, excessive current will flow if a differential input voltage in excess of 1V is applied between the inputs unless some limiting resistance is used.

Note 3: For supply voltages less than $\pm 15\text{V}$, the absolute maximum input voltage is equal to the supply voltage.

Note 4: These specifications apply for $\pm 5\text{V} \leq V_S \leq \pm 15\text{V}$ and $0^{\circ}\text{C} \leq T_A \leq +70^{\circ}\text{C}$, unless otherwise specified.

Typical Applications

Sample and Hold

†Teflon, polyethylene or polycarbonate dielectric capacitor.

Worst case drift less than 2.5 mV/sec.

TL/H/7759-4

High Speed Amplifier with Low Drift and Low Input Current

TL/H/7759-5

Application Hints

A very low drift amplifier poses some uncommon application and testing problems. Many sources of error can cause the apparent circuit drift to be much higher than would be predicted.

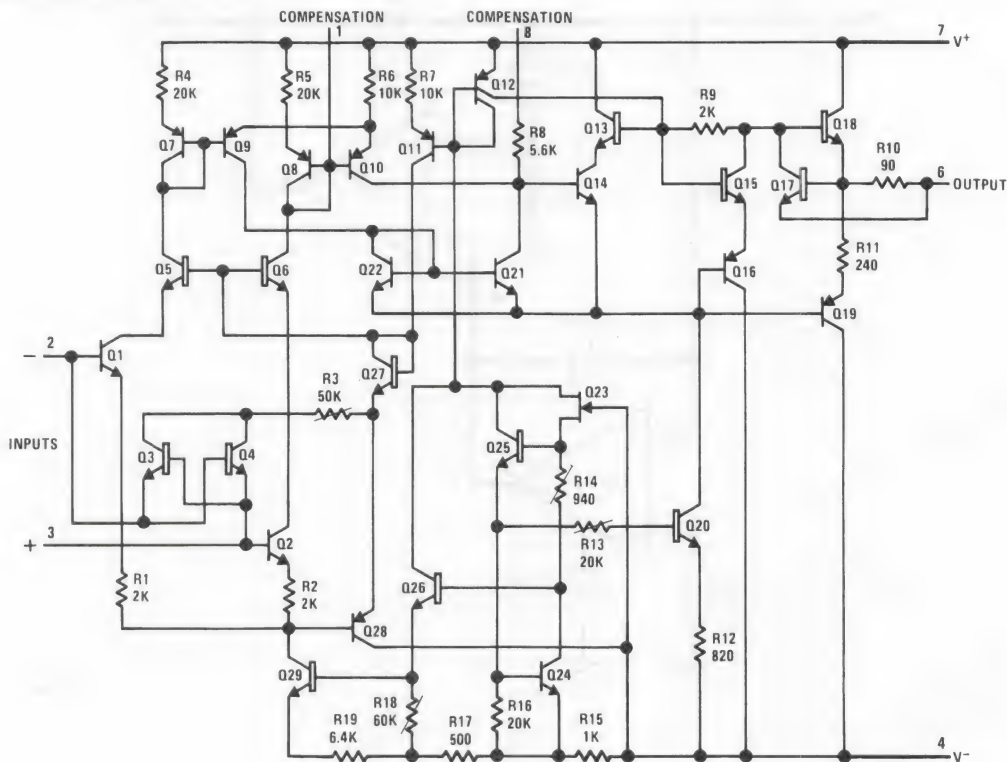

Thermocouple effects caused by temperature gradient across dissimilar metals are perhaps the worst offenders. Only a few degrees gradient can cause hundreds of microvolts of error. The two places this shows up, generally, are the package-to-printed circuit board interface and temperature gradients across resistors. Keeping package leads short and the two input leads close together helps greatly.

Resistor choice as well as physical placement is important for minimizing thermocouple effects. Carbon, oxide film and some metal film resistors can cause large thermocouple errors. Wirewound resistors of evanohm or manganin are best since they only generate about $2 \mu\text{V}/^\circ\text{C}$ referenced to copper. Of course, keeping the resistor ends at the same temperature is important. Generally, shielding a low drift stage electrically and thermally will yield good results.

Resistors can cause other errors besides gradient generated voltages. If the gain setting resistors do not track with temperature a gain error will result. For example, a gain of 1000 amplifier with a constant 10 mV input will have a 10V output. If the resistors mistrack by 0.5% over the operating temperature range, the error at the output is 50 mV. Referred to input, this is a $50 \mu\text{V}$ error. All of the gain fixing resistor should be the same material.

Testing low drift amplifiers is also difficult. Standard drift testing technique such as heating the device in an oven and having the leads available through a connector, thermoprobe, or the soldering iron method—do not work. Thermal gradients cause much greater errors than the amplifier drift. Coupling microvolt signal through connectors is especially bad since the temperature difference across the connector can be 50°C or more. The device under test along with the gain setting resistor should be isothermal.

LM112/LM212/LM312 Operational Amplifiers

General Description

The LM112 series are micropower operational amplifiers with very low offset-voltage and input-current errors—at least a factor of ten better than FET amplifiers over a -55°C to $+125^{\circ}\text{C}$ temperature range. Similar to the LM108 series, that also use supergain transistors, they differ in that they include internal frequency compensation and have provisions for offset adjustment with a single potentiometer.

These amplifiers will operate on supply voltages of $\pm 2\text{V}$ to $\pm 20\text{V}$, drawing a quiescent current of only $300\text{ }\mu\text{A}$. Performance is not appreciably affected over this range of voltages, so operation from unregulated power sources is easily accomplished. They can also be run from a single supply like the 5V used for digital circuits.

The LM112 series are the first IC amplifiers to improve reliability by including overvoltage protection for the MOS compensation capacitor. Without this feature, IC's have been

known to suffer catastrophic failure caused by short-duration overvoltage spikes on the supplies. Unlike other internally-compensated IC amplifiers, it is possible to overcompensate with an external capacitor to increase stability margin.

The LM212 is identical to the LM112, except that the LM212 has its performance guaranteed over a -25°C to $+85^{\circ}\text{C}$ temperature range instead of -55°C to $+125^{\circ}\text{C}$. The LM312 is guaranteed over a 0°C to $+70^{\circ}\text{C}$ temperature range.

Features

- Maximum input bias current of 3 nA over temperature
- Offset current less than 400 pA over temperature
- Low noise
- Guaranteed drift specifications

LM118/LM218/LM318 Operational Amplifiers

General Description

The LM118 series are precision high speed operational amplifiers designed for applications requiring wide bandwidth and high slew rate. They feature a factor of ten increase in speed over general purpose devices without sacrificing DC performance.

The LM118 series has internal unity gain frequency compensation. This considerably simplifies its application since no external components are necessary for operation. However, unlike most internally compensated amplifiers, external frequency compensation may be added for optimum performance. For inverting applications, feedforward compensation will boost the slew rate to over $150\text{V}/\mu\text{s}$ and almost double the bandwidth. Overcompensation can be used with the amplifier for greater stability when maximum bandwidth is not needed. Further, a single capacitor can be added to reduce the 0.1% settling time to under $1\mu\text{s}$.

The high speed and fast settling time of these op amps make them useful in A/D converters, oscillators, active fil-

ters, sample and hold circuits, or general purpose amplifiers. These devices are easy to apply and offer an order of magnitude better AC performance than industry standards such as the LM709.

The LM218 is identical to the LM118 except that the LM218 has its performance specified over a -25°C to $+85^{\circ}\text{C}$ temperature range. The LM318 is specified from 0°C to $+70^{\circ}\text{C}$.

Features

- 15 MHz small signal bandwidth
- Guaranteed $50\text{V}/\mu\text{s}$ slew rate
- Maximum bias current of 250 nA
- Operates from supplies of $\pm 5\text{V}$ to $\pm 20\text{V}$
- Internal frequency compensation
- Input and output overload protected
- Pin compatible with general purpose op amps

LM124/LM224/LM324/LM124A/LM224A/LM324A/LM2902

LM124/LM224/LM324, LM124A/LM224A/LM324A, LM2902 Low Power Quad Operational Amplifiers

General Description

The LM124 series consists of four independent, high gain, internally frequency compensated operational amplifiers which were designed specifically to operate from a single power supply over a wide range of voltages. Operation from split power supplies is also possible and the low power supply current drain is independent of the magnitude of the power supply voltage.

Application areas include transducer amplifiers, DC gain blocks and all the conventional op amp circuits which now can be more easily implemented in single power supply systems. For example, the LM124 series can be directly operated off of the standard +5 V_{DC} power supply voltage which is used in digital systems and will easily provide the required interface electronics without requiring the additional ± 15 V_{DC} power supplies.

Unique Characteristics

- In the linear mode the input common-mode voltage range includes ground and the output voltage can also swing to ground, even though operated from only a single power supply voltage.
- The unity gain cross frequency is temperature compensated.
- The input bias current is also temperature compensated.

Advantages

- Eliminates need for dual supplies
- Four internally compensated op amps in a single package
- Allows directly sensing near GND and V_{OUT} also goes to GND
- Compatible with all forms of logic
- Power drain suitable for battery operation

Features

- Internally frequency compensated for unity gain
- Large DC voltage gain 100 dB
- Wide bandwidth (unity gain) 1 MHz
- Wide power supply range:
 - Single supply 3 V_{DC} to 32 V_{DC}
 - or dual supplies ± 1.5 V_{DC} to ± 16 V_{DC}
- Very low supply current drain (800 μ A)—essentially independent of supply voltage (1 mW/op amp at +5 V_{DC})
- Low input biasing current 45 nA_{DC}
- Low input offset voltage (temperature compensated) 2 mV_{DC}
- Low input offset current and offset current 5 nA_{DC}
- Input common-mode voltage range includes ground
- Differential input voltage range equal to the power supply voltage
- Large output voltage swing 0 V_{DC} to V⁺ - 1.5 V_{DC}

	Sink $V_{IN}^+ = +1\text{ V}_{DC}, V_{IN}^- = 0\text{ V}_{DC}, V^+ = 15\text{ V}_{DC}$ $V_{IN}^- = +1\text{ V}_{DC}, V_{IN}^+ = 0\text{ V}_{DC}, V^+ = 15\text{ V}_{DC}$	10	15		5	8		5	8		5	8		

Note 1: For operating at high temperatures, the LM324/LM324A, LM2902 must be derated based on a $+125^\circ\text{C}$ maximum junction temperature and a thermal resistance of $88^\circ\text{C}/\text{W}$ which applies for the device soldered in a printed circuit board, operating in a still air ambient. The LM224/LM224A and LM124/LM124A can be derated based on a $+150^\circ\text{C}$ maximum junction temperature. The dissipation is the total of all four amplifiers—use external resistors, where possible, to allow the amplifier to saturate or to reduce the power which is dissipated in the integrated circuit.

Note 2: Short circuits from the output to V^+ can cause excessive heating and eventual destruction. When considering short circuits to ground, the maximum output current is approximately 40 mA independent of the magnitude of V^+ . At values of supply voltage in excess of $+15\text{ V}_{DC}$, continuous short-circuits can exceed the power dissipation ratings and cause eventual destruction. Destructive dissipation can result from simultaneous shorts on all amplifiers.

Note 3: This input current will only exist when the voltage at any of the input leads is driven negative. It is due to the collector-base junction of the input PNP transistors becoming forward biased and thereby acting as input diode clamps. In addition to this diode action, there is also lateral NPN parasitic transistor action on the IC chip. This transistor action can cause the output voltages of the op amps to go to the V^+ voltage level (or to ground for a large overdrive) for the time duration that an input is driven negative. This is not destructive and normal output states will re-establish when the input voltage, which was negative, again returns to a value greater than -0.3 V_{DC} (at 25°C).

Note 4: These specifications are limited to $-55^\circ\text{C} \leq T_A \leq +125^\circ\text{C}$ for the LM124/LM124A. With the LM224/LM224A, all temperature specifications are limited to $-25^\circ\text{C} \leq T_A \leq +85^\circ\text{C}$, the LM324/LM324A temperature specifications are limited to $0^\circ\text{C} \leq T_A \leq +70^\circ\text{C}$, and the LM2902 specifications are limited to $-40^\circ\text{C} \leq T_A \leq +85^\circ\text{C}$.

Note 5: $V_O \approx 1.4\text{ V}_{DC}$. $R_S = 0\Omega$ with V^+ from 5 V_{DC} to 30 V_{DC} ; and over the full input common-mode range (0 V_{DC} to $V^+ - 1.5\text{ V}_{DC}$) at 25°C ; for LM2902, V^+ from 5 V_{DC} to 26 V_{DC} .

Note 6: The direction of the input current is out of the IC due to the PNP input stage. This current is essentially constant, independent of the state of the output so no loading change exists on the input lines.

Note 7: The input common-mode voltage of either input signal voltage should not be allowed to go negative by more than 0.3 V (at 25°C). The upper end of the common-mode voltage range is $V^+ - 1.5\text{ V}$ (at 25°C), but either or both inputs can go to $+32\text{ V}_{DC}$ without damage ($+26\text{ V}_{DC}$ for LM2902), independent of the magnitude of V^+ .

Note 8: Due to proximity of external components, insure that coupling is not originating via stray capacitance between these external parts. This typically can be detected as this type of capacitance increases at higher frequencies.

Note 9: Refer to RETS124AX for LM124A military specifications and refer to RETS124X for LM124 military specifications.

Typical Performance Characteristics

Typical Performance Characteristics (LM2902 only)

TL/H/9299-4

Application Hints

The LM124 series are op amps which operate with only a single power supply voltage, have true-differential inputs, and remain in the linear mode with an input common-mode voltage of 0 V_{DC}. These amplifiers operate over a wide range of power supply voltage with little change in performance characteristics. At 25°C amplifier operation is possible down to a minimum supply voltage of 2.3 V_{DC}.

The pinouts of the package have been designed to simplify PC board layouts. Inverting inputs are adjacent to outputs for all of the amplifiers and the outputs have also been placed at the corners of the package (pins 1, 7, 8, and 14). Precautions should be taken to insure that the power supply for the integrated circuit never becomes reversed in polarity or that the unit is not inadvertently installed backwards in a test socket as an unlimited current surge through the resulting forward diode within the IC could cause fusing of the internal conductors and result in a destroyed unit.

Large differential input voltages can be easily accommodated and, as input differential voltage protection diodes are not needed, no large input currents result from large differential input voltages. The differential input voltage may be larger than V⁺ without damaging the device. Protection should be provided to prevent the input voltages from going negative more than -0.3 V_{DC} (at 25°C). An input clamp diode with a resistor to the IC input terminal can be used.

To reduce the power supply drain, the amplifiers have a class A output stage for small signal levels which converts to class B in a large signal mode. This allows the amplifiers to both source and sink large output currents. Therefore both NPN and PNP external current boost transistors can be used to extend the power capability of the basic amplifiers. The output voltage needs to raise approximately 1 diode drop above ground to bias the on-chip vertical PNP transistor for output current sinking applications.

For ac applications, where the load is capacitively coupled to the output of the amplifier, a resistor should be used, from the output of the amplifier to ground to increase the class A bias current and prevent crossover distortion.

Where the load is directly coupled, as in dc applications, there is no crossover distortion.

Capacitive loads which are applied directly to the output of the amplifier reduce the loop stability margin. Values of 50 pF can be accommodated using the worst-case non-inverting unity gain connection. Large closed loop gains or resistive isolation should be used if larger load capacitance must be driven by the amplifier.

The bias network of the LM124 establishes a drain current which is independent of the magnitude of the power supply voltage over the range of from 3 V_{DC} to 30 V_{DC}.

Output short circuits either to ground or to the positive power supply should be of short time duration. Units can be destroyed, not as a result of the short circuit current causing metal fusing, but rather due to the large increase in IC chip dissipation which will cause eventual failure due to excessive junction temperatures. Putting direct short-circuits on more than one amplifier at a time will increase the total IC power dissipation to destructive levels, if not properly protected with external dissipation limiting resistors in series with the output leads of the amplifiers. The larger value of output source current which is available at 25°C provides a larger output current capability at elevated temperatures (see typical performance characteristics) than a standard IC op amp.

The circuits presented in the section on typical applications emphasize operation on only a single power supply voltage. If complementary power supplies are available, all of the standard op amp circuits can be used. In general, introducing a pseudo-ground (a bias voltage reference of V⁺/2) will allow operation above and below this value in single power supply systems. Many application circuits are shown which take advantage of the wide input common-mode voltage range which includes ground. In most cases, input biasing is not required and input voltages which range to ground can easily be accommodated.

LM143/LM343 High Voltage Operational Amplifier

General Description

The LM143 is a general purpose high voltage operational amplifier featuring operation to $\pm 40\text{V}$, complete input overvoltage protection up to $\pm 40\text{V}$ and input currents comparable to those of other super- β op amps. Increased slew rate, together with higher common-mode and supply rejection, insure improved performance at high supply voltages. Operating characteristics, in particular supply current, slew rate and gain, are virtually independent of supply voltage and temperature. Furthermore, gain is unaffected by output loading at high supply voltages due to thermal symmetry on the die. The LM143 is pin compatible with general purpose op amps and has offset null capability.

Application areas include those of general purpose op amps, but can be extended to higher voltages and higher output power when externally boosted. For example, when used in audio power applications, the LM143 provides a power bandwidth that covers the entire audio spectrum. In addition, the LM143 can be reliably operated in environments with large overvoltage spikes on the power supplies, where other internally-compensated op amps would suffer catastrophic failure.

The LM343 is similar to the LM143 for applications in less severe supply voltage and temperature environments.

Features

- Wide supply voltage range $\pm 4.0\text{V}$ to $\pm 40\text{V}$
- Large output voltage swing $\pm 37\text{V}$
- Wide input common-mode range $\pm 38\text{V}$
- Input overvoltage protection Full $\pm 40\text{V}$
- Supply current is virtually independent of supply voltage and temperature

Unique Characteristics

- Low input bias current 8.0 nA
- Low input offset current 1.0 nA
- High slew rate—essentially independent of temperature and supply voltage $2.5\text{V}/\mu\text{s}$
- High voltage gain—virtually independent of resistive loading, temperature, and supply voltage 100k min
- Internally compensated for unity gain
- Output short circuit protection
- Pin compatible with general purpose op amps

Note 1: Absolute maximum ratings are not necessarily concurrent, and care must be taken not to exceed the maximum junction temperature of the LM143 (150°C) or the LM343 (100°C). For operating at elevated temperatures, devices in the TO-5 package must be derated based on a thermal resistance of 150°C/W , junction to ambient, or 45°C/W , junction to case.

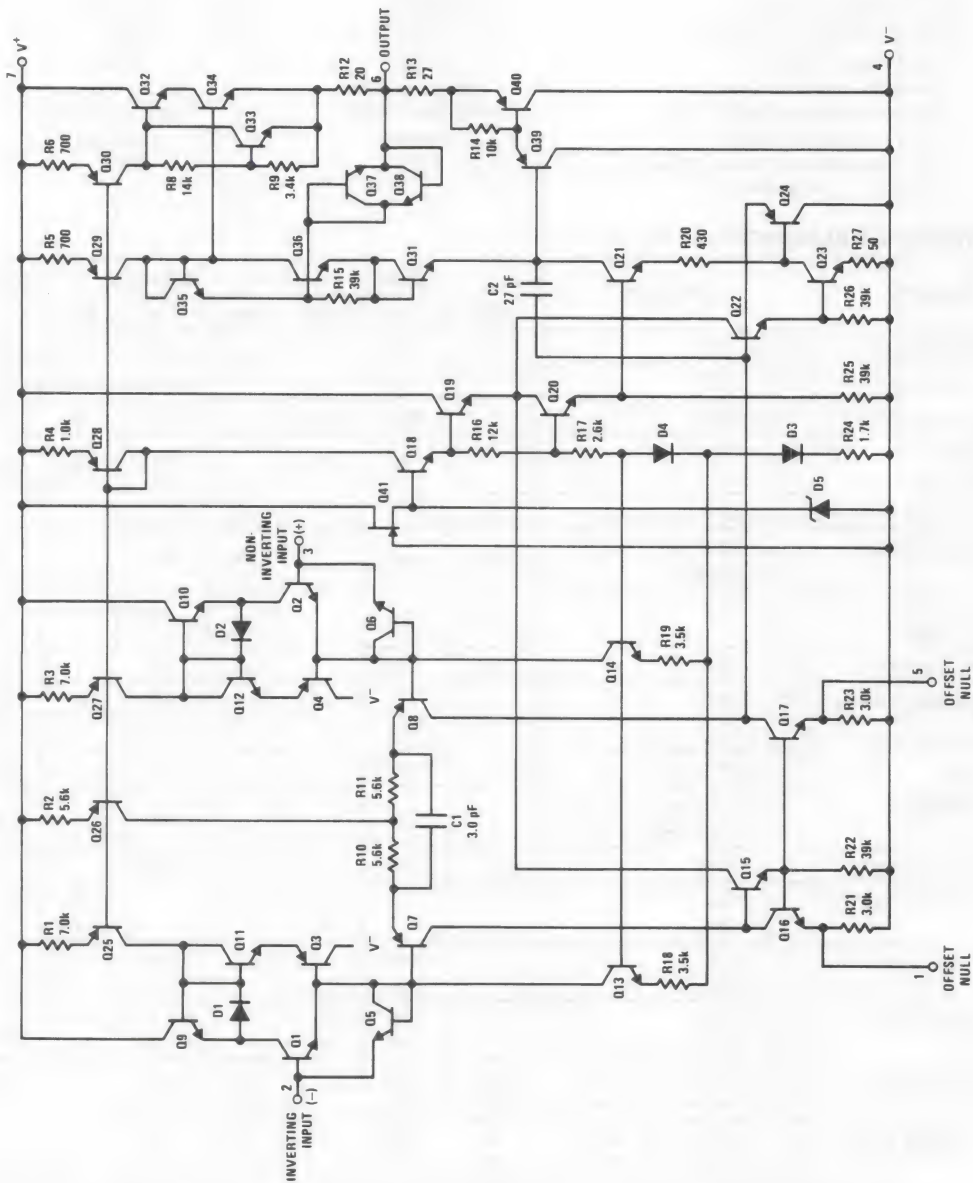

Note 2: For supply voltage less than $\pm 40\text{V}$ for the LM143 and less than $\pm 34\text{V}$ for the LM343, the absolute maximum input voltage is equal to the supply voltage.

Note 3: These specifications apply for $V_S = \pm 28\text{V}$. For LM143, $T_A = \text{max} = 125^{\circ}\text{C}$ and $T_A = \text{min} = -55^{\circ}\text{C}$. For LM343, $T_A = \text{max} = 70^{\circ}\text{C}$ and $T_A = \text{min} = 0^{\circ}\text{C}$.

Note 4: Refer to RETS143X for LM143H and LM1536H military specifications.

Note 5: The maximum supply currents are guaranteed at $V_S = \pm 40\text{V}$ for the LM143 and $V_S = \pm 34\text{V}$ for the LM343.

Application Hints (See AN-127)

The LM143 is designed for trouble free operation at any supply voltage up to and including the guaranteed maximum of $\pm 40\text{V}$. Input overvoltage protection, both common-mode and differential, is 100% tested and guaranteed at the maximum supply voltage. Furthermore, all possible high voltage destructive modes during supply voltage turn-on have been eliminated by design. As with most IC op amps, however, certain precautions should be observed to insure that the LM143 remains virtually blow-out proof.

Although output short circuits to ground or either supply can be sustained indefinitely at lower supply voltages, these short circuits should be of limited duration when operating at higher supply voltages. Units can be destroyed by any combination of high ambient temperature, high supply voltages, and high power dissipation which results in excessive die temperature. This is also true when driving low impedance or reactive loads or loads that can revert to low impedance; for example, the LM143 can drive most general purpose op amps outside of the maximum input voltage range, causing heavy current to flow and possibly destroying both devices.

Precautions should be taken to insure that the power supplies never become reversed in polarity—even under transient conditions. With reverse voltage, the IC will conduct excessive current, fusing the internal aluminum interconnects. Voltage reversal between the power supplies will almost always result in a destroyed unit.

In high voltage applications which are sensitive to very low input currents, special precautions should be exercised. For example, with high source resistances, care should be taken to prevent the magnitude of the PC board leakage currents, although quite small, from approaching those of the op amp input currents. These leakage currents become larger at 125°C and are made worse by high supply voltages. To prevent this, PC boards should be properly cleaned and coated to prevent contamination and to provide protection from condensed water vapor when operating below 0°C . A guard ring is also recommended to significantly reduce leakage currents from the op amp input pins to the adjacent high voltage pins in the standard op amp pin connection as shown in Figure 1. Figures 2, 3 and 4 show how the guard ring is connected for the three most common op amp configurations.

Finally, caution should be exercised in high voltage applications as electrical shock hazards are present. Since the negative supply is connected to the case, users may inadvertently contact voltages equal to those across the power supplies.

The LM143 can be used as a plug-in replacement in most general purpose op amp applications. The circuits presented in the following section emphasize those applications which take advantage of the unique high voltage abilities of the LM143.

LM144/LM344 High Voltage, High Slew Rate Operational Amplifier

General Description

The LM144 is a general purpose high voltage, uncompensated operational amplifier featuring operation to $\pm 36\text{V}$, complete input overvoltage protection up to the supply voltages and input currents comparable to those of other super- β op amps. Increased slew rate, together with high common-mode and supply rejection, insure excellent performance at high supply voltages. Operating characteristics, in particular supply current, slew rate and gain, are virtually independent of supply voltage and temperature. Furthermore, due to thermal symmetry on the die, gain is unaffected by output loading at high supply voltages.

With the unique advantages of low input current, high gain, and high slew rate, the LM144 can increase accuracy and useful frequency range in many existing applications. For example, the LM144 is a plug-in replacement for the LM101A, as well as other general purpose op amps.

The LM144 can be compensated with a single capacitor, thus giving the user the ability to optimize ac parameters to suit the application. For example, in applications such as audio power amplifiers, the LM144 with a gain of 10 can provide a $\pm 30\text{V}$ output swing, a slew rate of approximately $30\text{V}/\mu\text{s}$, and a 120 kHz full power bandwidth.

In applications where capacitive loads or cables must be driven, the LM144 can be overcompensated for increased stability.

The LM344 is similar to the LM144 for applications in less severe supply voltage and temperature environments.

Features

- External compensation provides large power bandwidth ($A_V \geq 10$) 120 kHz
- Wide operating voltage range $\pm 4.0\text{V}$ to $\pm 36\text{V}$
- Large output voltage swing $\pm 30\text{V}$
- Wide input common-mode range
- Input overvoltage protection
- Electrical characteristics independent of supply voltage and temperature

Unique Characteristics

- Low input bias current 8.0 nA
- Low input offset current 1.0 nA
- High slew rate ($A_V \geq 10$) $30\text{V}/\mu\text{s}$
- High voltage gain 100k min
- Offset voltage null capability

Typical Application

Large Power Bandwidth, Current Boosted Audio Line Driver

	$T_A = \text{Min}$			6.0			10	mV
Input Offset Current	$T_A = \text{Max}$		0.8	4.5		0.8	14	nA
	$T_A = \text{Min}$		1.8	7.0		1.8	14	nA
Input Bias Current	$T_A = \text{Max}$		5.0	35		5.0	55	nA
	$T_A = \text{Min}$		16	35		16	55	nA
Large Signal Voltage Gain	$R_L \geq 100\text{ k}\Omega$, $T_A = \text{Max}$	50k	150k		50k	150k		V/V
	$R_L \geq 100\text{ k}\Omega$, $T_A = \text{Min}$	50k	220k		50k	220k		V/V
Output Voltage Swing	$R_L \geq 5.0\text{ k}\Omega$, $T_A = \text{Max}$	22	26		20	26		V
	$R_L \geq 5.0\text{ k}\Omega$, $T_A = \text{Min}$	22	25		20	25		V

Note 1: The maximum junction temperature of the LM144 is 150°C , while that of the LM344 is 100°C . For operating at elevated temperatures, devices in the TO-5 package must be derated based on a thermal resistance of 150°C/W , junction to ambient, or 45°C/W , junction to case.

Note 2: For supply voltage less than $\pm 40\text{V}$ for the LM144 and less than $\pm 34\text{V}$ for the LM344, the absolute maximum input voltage is equal to the supply voltage.

Note 3: These specifications apply for $V_S = \pm 28\text{V}$. For the LM144, $T_A = \text{max} = 125^{\circ}\text{C}$ and $T_A = \text{min} = -55^{\circ}\text{C}$. For the LM344, $T_A = \text{max} = 70^{\circ}\text{C}$ and $T_A = \text{min} = 0^{\circ}\text{C}$.

Note 4: Refer to RETS144X for LM144H specifications.

Application Hints (See Also AN-127)

The LM144 is designed for trouble-free operation at any supply voltage up to a maximum of $\pm 40\text{V}$. Input overvoltage protection, both common-mode and differential, is 100% tested and guaranteed at the maximum supply voltage. Furthermore, all possible high voltage destructive modes during supply voltage turn-on have been eliminated by design. As with most IC op amps, however, certain precautions should be observed to insure that the LM144 remains virtually blow-out proof.

Although output short circuits to ground or either supply can be sustained indefinitely for supply voltages, below $\pm 18\text{V}$, these short circuits should be of limited duration when operating at higher supply voltages. Units can be destroyed by any combination of high ambient temperature, high supply voltages, and high power dissipation which results in excessive die temperature. This is also true when driving low impedance or reactive loads or loads that can revert to low impedance; for example, the LM144 can drive most general purpose op amps outside of their maximum input voltage range, causing heavy current to flow and possibly destroying both devices.

Precautions should be taken to insure that the power supplies never become reversed in polarity—even under transient conditions. With reverse voltage, the IC will conduct excessive current, fusing the internal aluminum interconnects. Voltage reversal between the power supplies will almost always result in a destroyed unit.

In high voltage applications which are sensitive to very low input currents, special precautions should be exercised.

$$R3 \times \frac{R1 \times R2}{R1 + R2} = R_{SOURCE}$$

TL/H/7784-7

FIGURE 3. Guarded Non-Inverting Amplifier

For example, with high source resistances, care should be taken to prevent the magnitude of the PC board leakage currents, although quite small, from approaching those of the op amp input currents. These leakage currents become larger at 125°C and are made worse by high supply voltages. To prevent this, PC boards should be properly cleaned and coated to prevent contamination and to provide protection from condensed water vapor when operating below 0°C . A guard ring is also recommended to significantly reduce leakage currents from the op amp input pins to the adjacent high voltage pins in the standard op amp pin connection as shown in Figure 1. Figures 2, 3 and 4 show how the guard ring is connected for the three most common op amp configurations.

The minimum values given for the frequency compensation capacitor are stable only for source resistances less than $10\text{ k}\Omega$, stray capacitances on the summing junction less than 5 pF and capacitive loads smaller than 100 pF . If any of these conditions are not met, it becomes necessary to overcompensate the amplifier with a larger compensation capacitor. Alternately, lead capacitors can be used in the feedback network to negate the effect of stray capacitance and large feedback resistors or an RC network can be added to isolate capacitive loads. See Figures 5, 6 and 7.

Finally, caution should be exercised in high voltage applications as electrical shock hazards are present. Since the negative supply is connected to the case, users may inadvertently contact voltages equal to those across the power supplies.

LM146/LM246/LM346 Programmable Quad Operational Amplifiers

General Description

The LM146 series of quad op amps consists of four independent, high gain, internally compensated, low power, programmable amplifiers. Two external resistors (R_{SET}) allow the user to program the gain bandwidth product, slew rate, supply current, input bias current, input offset current and input noise. For example, the user can trade-off supply current for bandwidth or optimize noise figure for a given source resistance. In a similar way, other amplifier characteristics can be tailored to the application. Except for the two programming pins at the end of the package, the LM146 pin-out is the same as the LM124 and LM148.

Features ($I_{SET} = 10 \mu A$)

- Programmable electrical characteristics
- Battery-powered operation
- Low supply current 350 μA amplifier
- Guaranteed gain bandwidth product 0.8 MHz min
- Large DC voltage gain 120 dB
- Low noise voltage 28 nV/\sqrt{Hz}
- Wide power supply range $\pm 1.5V$ to $\pm 22V$
- Class AB output stage—no crossover distortion
- Ideal pin out for Biquad active filters
- Input bias currents are temperature compensated

DC Electrical Characteristics ($V_S = \pm 1.5V$, $I_{SET} = 10 \mu A$)

Parameter	Conditions	LM146			LM246/LM346			Units
		Min	Typ	Max	Min	Typ	Max	
Input Offset Voltage	$V_{CM} = 0V$, $R_S \leq 50 \Omega$, $T_A = 25^\circ C$		0.5	5		0.5	7	mV
Input CM Range	$T_A = 25^\circ C$	± 0.7			± 0.7			V
CM Rejection Ratio	$R_S \leq 50 \Omega$, $T_A = 25^\circ C$		80			80		dB
Output Voltage Swing	$R_L \geq 10 k\Omega$, $T_A = 25^\circ C$	± 0.6			± 0.6			V

Note 1: For supply voltages less than $\pm 15V$, the absolute maximum input voltage is equal to the supply voltage.

Note 2: The maximum power dissipation for these devices must be derated at elevated temperatures and is dictated by T_{JMAX} , θ_{JA} , and the ambient temperature, T_A . The maximum available power dissipation at any temperature is $P_D = (T_{JMAX} - T_A) / \theta_{JA}$ or the $25^\circ C$ P_{DMAX} , whichever is less.

Note 3: Any of the amplifier outputs can be shorted to ground indefinitely; however, more than one should not be simultaneously shorted as the maximum junction temperature will be exceeded.

Note 4: These specifications apply over the absolute maximum operating temperature range unless otherwise noted.

Note 5: Refer to RETS146X for LM146J military specifications.

Application Hints

Avoid reversing the power supply polarity; the device will fail.

Common-Mode Input Voltage: The negative common-mode voltage limit is one diode drop above the negative supply voltage. Exceeding this limit on either input will result in an output phase reversal. The positive common-mode limit is typically 1V below the positive supply voltage. No output phase reversal will occur if this limit is exceeded by either input.

Output Voltage Swing vs I_{SET} : For a desired output voltage swing the value of the minimum load depends on the positive and negative output current capability of the op amp. The maximum available positive output current, (I_{CL+}), of the device increases with I_{SET} whereas the negative output current (I_{CL-}) is independent of I_{SET} . *Figure 1* illustrates the above.

FIGURE 1. Output Current Limit vs I_{SET}

TL/H/5654-7

Input Capacitance: The input capacitance, C_{IN} , of the LM146 is approximately 2 pF; any stray capacitance, C_S , (due to external circuit circuit layout) will add to C_{IN} . When resistive or active feedback is applied, an additional pole is added to the open loop frequency response of the device. For instance with resistive feedback (*Figure 2*), this pole occurs at $\frac{1}{2\pi} (R_1 || R_2) (C_{IN} + C_S)$. Make sure that this pole occurs at least 2 octaves beyond the expected -3 dB frequency corner of the closed loop gain of the amplifier; if not, place a lead capacitor in the feedback such that the time constant of this capacitor and the resistance it parallels is equal to the $R_I(C_S + C_{IN})$, where R_I is the input resistance of the circuit.

FIGURE 2

TL/H/5654-9

Temperature Effect on the GBW: The GBW (gain bandwidth product), of the LM146 is directly proportional to I_{SET} and inversely proportional to the absolute temperature. When using resistors to set the bias current, I_{SET} , of the device, the GBW product will decrease with increasing temperature. Compensation can be provided by creating an I_{SET} current directly proportional to temperature (see typical applications).

Isolation Between Amplifiers: The LM146 die is isothermally laid out such that crosstalk between *all 4* amplifiers is in excess of -105 dB (DC). Optimum isolation (better than -110 dB) occurs between amplifiers A and D, B and C; that is, if amplifier A dissipates power on its output stage, amplifier D is the one which will be affected the least, and vice versa. Same argument holds for amplifiers B and C.

LM146 Typical Performance Summary: The LM146 typical behaviour is shown in *Figure 3*. The device is fully predictable. As the set current, I_{SET} , increases, the speed, the bias current, and the supply current increase while the noise power decreases proportionally and the V_{OS} remains constant. The usable GBW range of the op amp is 10 kHz to 3.5–4 MHz.

FIGURE 3. LM146 Typical Characteristics

TL/H/5654-8

Low Power Supply Operation: The quad op amp operates down to $\pm 1.3\text{V}$ supply. Also, since the internal circuitry is biased through programmable current sources, no degradation of the device speed will occur.

Speed vs Power Consumption: LM146 vs LM4250 (single programmable). Through *Figure 4*, we observe that the LM146's power consumption has been optimized for GBW products above 200 kHz, whereas the LM4250 will reach a GBW of no more than 300 kHz. For GBW products below 200 kHz, the LM4250 will consume less power.

FIGURE 4. LM146 vs LM4250

TI/H/5654-10

Typical Applications

Dual Supply or Negative Supply Biasing

$$I_{SET} \approx \frac{|V^-| - 0.6V}{R_{SET}}$$

Single (Positive) Supply Biasing

$$I_{SET} \approx \frac{V^+ - 0.6V}{R_{SET}}$$

Current Source Biasing with Temperature Compensation

$$I_{SET} = \frac{67.7 \text{ mV}}{R_{SET}}$$

- The LM334 provides an I_{SET} directly proportional to absolute temperature. This cancels the slight GBW product Temperature coefficient of the LM346.

Biasing all 4 Amplifiers with Single Current Source

$$\frac{I_{SET1}}{I_{SET2}} = \frac{R2}{R1}, I_{SET1} + I_{SET2} = \frac{67.7 \text{ mV}}{R_{SET}}$$

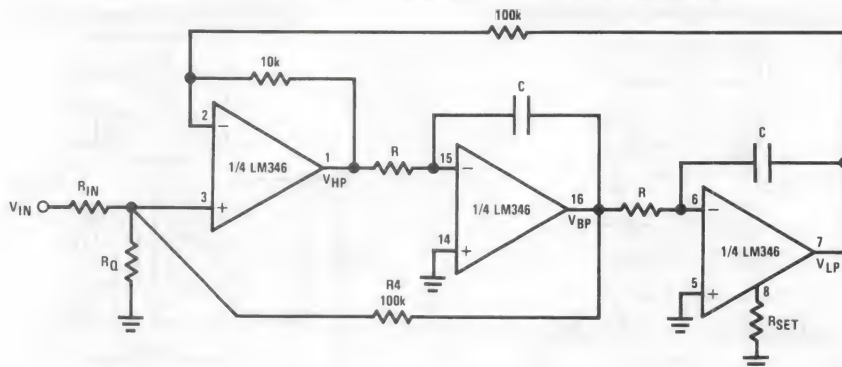

- For $I_{SET1} \approx I_{SET2}$ resistors $R1$ and $R2$ are not required if a slight error between the 2 set currents can be tolerated. If not, then use $R1 = R2$ to create a 100 mV drop across these resistors.

TL/H/5654-11

2

Active Filters Applications

Basic (Non-Inverting "State Variable") Active Filter Building Block

TL/H/5654-12

- The LM146 quad programmable op amp is especially suited for active filters because of their adequate GBW product and low power consumption.

Circuit synthesis equations (for circuit analysis equations, consult with the LM148 data sheet).

Need to know desired: f_o = center frequency measured at the BP output

Q_o = quality factor measured at the BP output

H_o = gain at the output of interest (BP or HP or all of them)

- Relation between different gains: $H_o(BP) = 0.316 \times Q_o \times H_o(LP)$; $H_o(LP) = 10 \times H_o(HP)$

- $R \times C = \frac{5.033 \times 10^{-2}}{f_o} \text{ (sec)}$

- For BP output: $R_Q = \left(\frac{3.478 Q_o - H_o(BP)}{10^5} - \frac{H_o(BP)}{10^5 \times 3.478 \times Q_o} \right)^{-1}$; $R_{IN} = \frac{(3.478 Q_o - 1)}{\frac{H_o(BP)}{R_Q} + 10^{-5}}$

- For HP output: $R_Q = \frac{1.1 \times 10^5}{3.478 Q_o (1.1 - H_o(HP)) - H_o(HP)}$; $R_{IN} = \frac{\frac{1.1}{H_o(HP)} - 1}{\frac{1}{R_Q} + 10^{-5}}$

Note. All resistor values are given in ohms.

- For LP output: $R_Q = \frac{11 \times 10^5}{3.478 Q_o (11 - H_o(LP)) - H_o(LP)}$; $R_{IN} = \frac{\frac{11}{H_o(LP)} - 1}{\frac{1}{R_Q} + 10^{-5}}$

- For BR (notch) output: Use the 4th amplifier of the LM146 to sum the LP and HP outputs of the basic filter.

$$\sqrt{\frac{R_H}{R_L}} = 0.316 \frac{f_{notch}}{f_o}$$

TL/H/5654-13

Determine R_F according to the desired gains: $H_o(BR) \Big|_{f < f_{notch}} = \frac{R_F}{R_L} H_o(LP)$, $H_o(BR) \Big|_{f > f_{notch}} = \frac{R_F}{R_H} H_o(HP)$

- Where to use amplifier C:** Examine the above gain relations and determine the dynamics of the filter. Do not allow slew rate limiting in any output (V_{HP} , V_{BP} , V_{LP}), that is:

$$V_{IN(peak)} < 63.66 \times 10^3 \times \frac{I_{SET}}{10 \mu A} \times \frac{1}{f_o \times H_o} \text{ (Volts)}$$

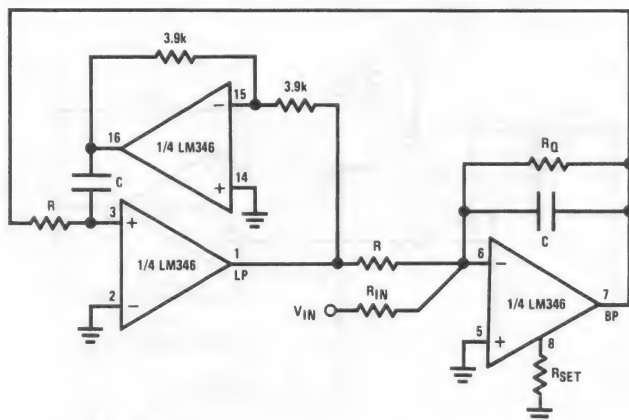

If necessary, use amplifier C, biased at higher I_{SET} , where you get the largest output swing.

Deviation from Theoretical Predictions: Due to the finite GBW products of the op amps the f_o , Q_o will be slightly different from the theoretical predictions.

$$f_{real} \approx \frac{f_o}{1 + \frac{2 f_o}{GBW}}, \quad Q_{real} \approx \frac{Q_o}{1 - \frac{3.2 f_o \times Q_o}{GBW}}$$

Active Filters Applications (Continued)

A Simple-to-Design BP, LP Filter Building Block

TL/H/5654-14

- If resistive biasing is used to set the LM346 performance, the Q_0 of this filter building block is nearly insensitive to the op amp's GBW product temperature drift; it has also better noise performance than the state variable filter.

Circuit Synthesis Equations

$$H_0(\text{BP}) = Q_0 H_0(\text{LP}); R \times C = \frac{0.159}{f_0}; R_Q = Q_0 \times R; R_{IN} = \frac{R_Q}{H_0(\text{BP})} = \frac{R}{H_0(\text{LP})}$$

- For the eventual use of amplifier C, see comments on the previous page.

A 3-Amplifier Notch Filter (or Elliptic Filter Building Block)

TL/H/5654-15

Circuit Synthesis Equations

$$R \times C = \frac{0.159}{f_0}; R_Q = Q_0 \times R; R_{IN} = \frac{0.159 \times f_0}{C' \times f_{\text{notch}}^2}$$

$$H_0(\text{BR})|_{f < f_{\text{notch}}} = \frac{R}{R_{IN}} H_0(\text{BR})|_{f > f_{\text{notch}}} = \frac{C'}{C}$$

- For nothing but a notch output: $R_{IN} = R$, $C' = C$.

Active Filters Applications (Continued)

Capacitorless Active Filters (Basic Circuit)

TL/H/5654-16

- This is a BP, LP, BR filter. The filter characteristics are created by using the tunable frequency response of the LM346.

- Limitations:** $Q_0 < 10$, $f_0 \times Q_0 < 1.5$ MHz, output voltage should not exceed $V_{peak(out)} \leq \frac{63.66 \times 10^3}{f_0} \times \frac{I_{SET}(\mu A)}{10 \mu A}$ (V)

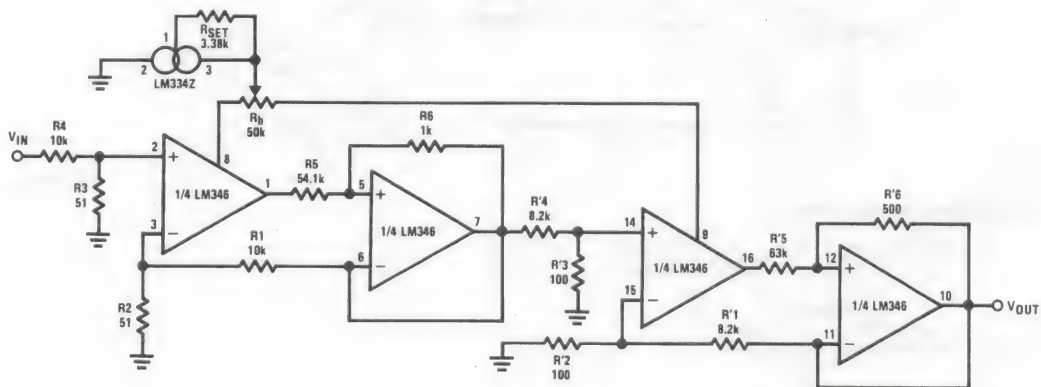

- Design equations: $a = \frac{R6 + R5}{R6}$, $b = \frac{R2}{R1 + R2}$, $c = \frac{R3}{R3 + R4}$, $d = \frac{R7}{R8 + R7}$, $e = \frac{R10}{R10 + R9}$, $f_0(BP) = f_u \sqrt{\frac{b}{a}}$, $H_0(BP) = a \times c$, $H_0(LP) = \frac{c}{b}$, $Q_0 = \sqrt{a \times b}$
 $f_0(BR) = f_0(BP) \left(1 - \frac{c}{b}\right) \approx f_0(BP) (C < 1)$ provided that $d = H_0(BP) \times e$, $H_0(BR) = \frac{R10}{R9}$.

- Advantage: $f_0 Q_0$, H_0 can be independently adjusted; that is, the filter is extremely easy to tune.

- Tuning procedure (ex. BP tuning)

- Pick up a convenient value for b; ($b < 1$)
- Adjust Q_0 through R5
- Adjust $H_0(BP)$ through R4
- Adjust f_0 through RSET

A 4th Order Butterworth Low Pass Capacitorless Filter

TL/H/5654-17

Ex: $f_c = 20$ kHz, H_0 (gain of the filter) = 1, $Q_{01} = 0.541$, $Q_{02} = 1.306$.

- Since for this filter the GBW product of all 4 amplifiers has been designed to be the same (~ 1 MHz) only one current source can be used to bias the circuit. Fine tuning can be further accomplished through R_6 .

Miscellaneous Applications

A Unity Gain Follower with Bias Current Reduction

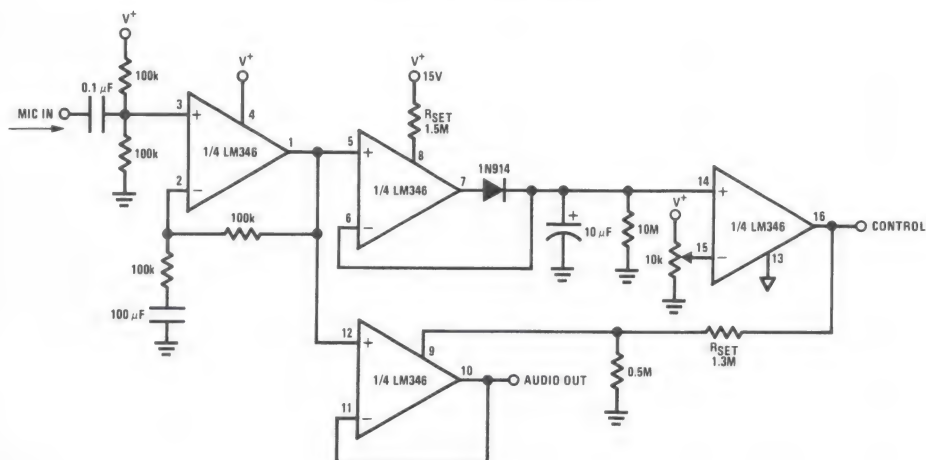

• For better performance, use a matched NPN pair.

Circuit Shutdown

• By pulling the SET pin(s) to V^- the op amp(s) shuts down and its output goes to a high impedance state. According to this property, the LM346 can be used as a very low speed analog switch.

Voice Activated Switch and Amplifier

LM148/LM149 Series Quad 741 Op Amp

LM148/LM248/LM348 Quad 741 Op Amps

LM149/LM249/LM349 Wide Band Decompensated ($A_V(\text{MIN}) = 5$)

General Description

The LM148 series is a true quad 741. It consists of four independent, high gain, internally compensated, low power operational amplifiers which have been designed to provide functional characteristics identical to those of the familiar 741 operational amplifier. In addition the total supply current for all four amplifiers is comparable to the supply current of a single 741 type op amp. Other features include input offset currents and input bias current which are much less than those of a standard 741. Also, excellent isolation between amplifiers has been achieved by independently biasing each amplifier and using layout techniques which minimize thermal coupling. The LM149 series has the same features as the LM148 plus a gain bandwidth product of 4 MHz at a gain of 5 or greater.

The LM148 can be used anywhere multiple 741 or 1558 type amplifiers are being used and in applications where amplifier matching or high packing density is required.

Features

- 741 op amp operating characteristics
- Low supply current drain 0.6 mA/Amplifier
- Class AB output stage—no crossover distortion
- Pin compatible with the LM124
- Low input offset voltage 1 mV
- Low input offset current 4 nA
- Low input bias current 30 nA
- Gain bandwidth product
 - LM148 (unity gain) 1.0 MHz
 - LM149 ($A_V \geq 5$) 4 MHz
- High degree of isolation between amplifiers 120 dB
- Overload protection for inputs and outputs

Electrical Characteristics (Note 3) (Continued)

Parameter	Conditions	LM148/LM149			LM248/LM249			LM348/LM349			Units
		Min	Typ	Max	Min	Typ	Max	Min	Typ	Max	
Large Signal Voltage Gain	$V_S = \pm 15V$, $V_{OUT} = \pm 10V$, $R_L > 2 k\Omega$	25			15			15			V/mV
Output Voltage Swing	$V_S = \pm 15V$, $R_L = 10 k\Omega$ $R_L = 2 k\Omega$	± 12 ± 10	± 13 ± 12		± 12 ± 10	± 13 ± 12		± 12 ± 10	± 13 ± 12		V V
Input Voltage Range	$V_S = \pm 15V$	± 12			± 12			± 12			V
Common-Mode Rejection Ratio	$R_S \leq 10 k\Omega$	70	90		70	90		70	90		dB
Supply Voltage Rejection	$R_S \leq 10 k\Omega$, $\pm 5V \leq V_S \leq \pm 15V$	77	96		77	96		77	96		dB

Note 1: Any of the amplifier outputs can be shorted to ground indefinitely; however, more than one should not be simultaneously shorted as the maximum junction temperature will be exceeded.

Note 2: The maximum power dissipation for these devices must be derated at elevated temperatures and is dictated by T_{JMAX} , θ_{JA} , and the ambient temperature, T_A . The maximum available power dissipation at any temperature is $P_d = (T_{JMAX} - T_A)/\theta_{JA}$ or the $25^\circ C$ P_{dMAX} , whichever is less.

Note 3: These specifications apply for $V_S = \pm 15V$ and over the absolute maximum operating temperature range ($T_L \leq T_A \leq T_H$) unless otherwise noted.

Note 4: Refer to RETS 148X for LM148 military specifications.

$$\text{Crosstalk} = -20 \log \frac{e^{\circ} \text{OUT}}{101 \times e^{\circ} \text{OUT}} (\text{dB})$$

$$V_S = \pm 15V$$

Application Hints

The LM148 series are quad low power 741 op amps. In the proliferation of quad op amps, these are the first to offer the convenience of familiar, easy to use operating characteristics of the 741 op amp. In those applications where 741 op amps have been employed, the LM148 series op amps can be employed directly with no change in circuit performance.

The LM149 series has the same characteristics as the LM148 except it has been decompensated to provide a wider bandwidth. As a result the part requires a minimum gain of 5.

The package pin-outs are such that the inverting input of each amplifier is adjacent to its output. In addition, the amplifier outputs are located in the corners of the package which simplifies PC board layout and minimizes package related capacitive coupling between amplifiers.

The input characteristics of these amplifiers allow differential input voltages which can exceed the supply voltages. In addition, if either of the input voltages is within the operating common-mode range, the phase of the output remains correct. If the negative limit of the operating common-mode range is exceeded at both inputs, the output voltage will be positive. For input voltages which greatly exceed the maximum supply voltages, either differentially or common-mode, resistors should be placed in series with the inputs to limit the current.

Like the LM741, these amplifiers can easily drive a 100 pF capacitive load throughout the entire dynamic output voltage and current range. However, if very large capacitive loads must be driven by a non-inverting unity gain amplifier, a resistor should be placed between the output (and feed-

back connection) and the capacitance to reduce the phase shift resulting from the capacitive loading.

The output current of each amplifier in the package is limited. Short circuits from an output to either ground or the power supplies will not destroy the unit. However, if multiple output shorts occur simultaneously, the time duration should be short to prevent the unit from being destroyed as a result of excessive power dissipation in the IC chip.

As with most amplifiers, care should be taken lead dress, component placement and supply decoupling in order to ensure stability. For example, resistors from the output to an input should be placed with the body close to the input to minimize "pickup" and maximize the frequency of the feedback pole which capacitance from the input to ground creates.

A feedback pole is created when the feedback around any amplifier is resistive. The parallel resistance and capacitance from the input of the device (usually the inverting input) to AC ground set the frequency of the pole. In many instances the frequency of this pole is much greater than the expected 3 dB frequency of the closed loop gain and consequently there is negligible effect on stability margin. However, if the feedback pole is less than approximately six times the expected 3 dB frequency a lead capacitor should be placed from the output to the input of the op amp. The value of the added capacitor should be such that the RC time constant of this capacitor and the resistance it parallels is greater than or equal to the original feedback pole time constant.

TL/H/7786-5

Typical Applications—LM148

One Decade Low Distortion Sinewave Generator

$$f = \frac{1}{2\pi R_1 C_1} \times \sqrt{K}, K = \frac{R_4 R_5}{R_3} \left(\frac{1}{r_{DS}} + \frac{1}{R_4} + \frac{1}{R_5} \right), r_{DS} \approx \frac{R_{ON}}{\left(1 - \frac{V_{GS}}{V_P} \right)^{1/2}}$$

TL/H/7786-8

$f_{MAX} = 5 \text{ kHz}$, THD $\leq 0.03\%$

$R_1 = 100k \text{ pot}$, $C_1 = 0.0047 \mu\text{F}$, $C_2 = 0.01 \mu\text{F}$, $C_3 = 0.1 \mu\text{F}$, $R_2 = R_6 = R_7 = 1M$,
 $R_3 = 5.1k$, $R_4 = 12\Omega$, $R_5 = 240\Omega$, $Q = \text{NS5102}$, $D_1 = 1N914$, $D_2 = 3.6V \text{ avalanche diode (ex. LM103)}$, $V_S = \pm 15V$

A simpler version with some distortion degradation at high frequencies can be made by using A1 as a simple inverting amplifier, and by putting back to back zeners in the feedback loop of A3.

Low Cost Instrumentation Amplifier

$$V_{OUT} = 2 \left(\frac{2R}{R_1} + 1 \right), V_S - 3V \leq V_{IN CM} \leq V_S + 3V,$$

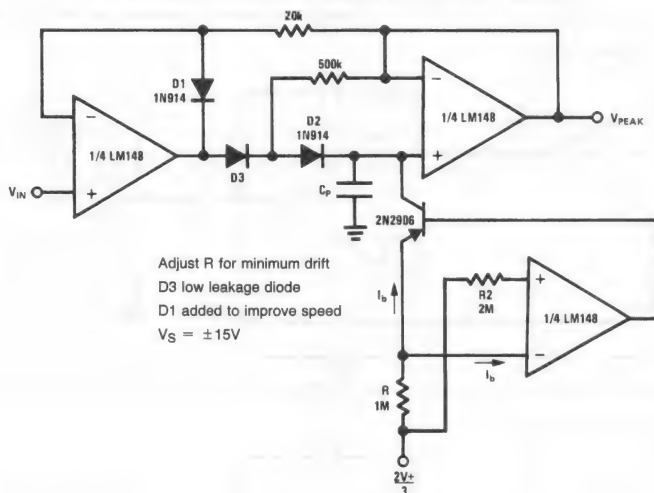

TL/H/7786-9

$V_S = \pm 15V$

$R = R_2$, trim R_2 to boost CMRR

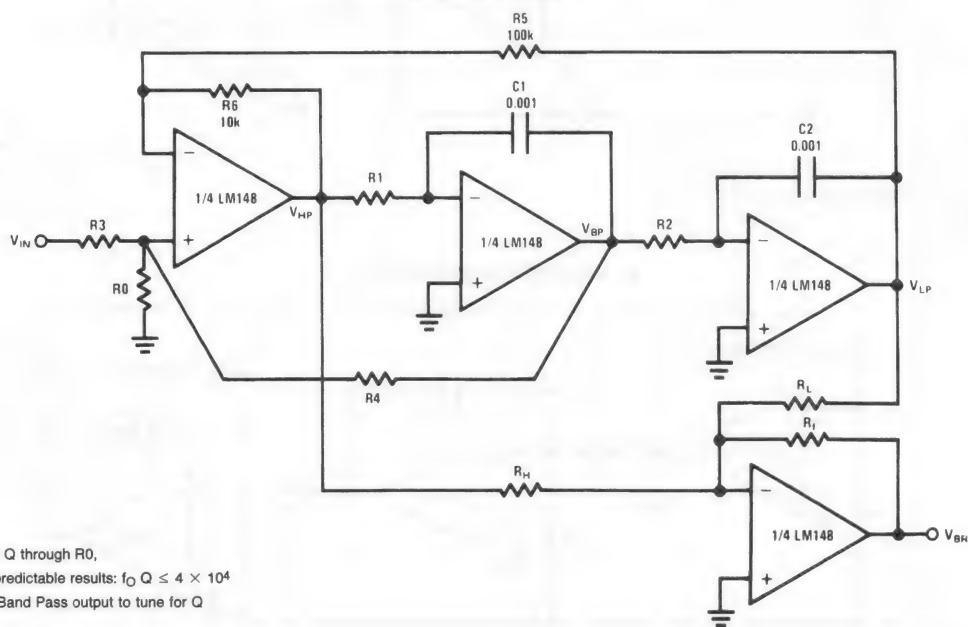

Typical Applications—LM148 (Continued)

Low Drift Peak Detector with Bias Current Compensation

TL/H/7786-10

Universal State-Space Filter

Tune Q through R0.

For predictable results: $f_0 Q \leq 4 \times 10^4$

Use Band Pass output to tune for Q

$$\frac{V(s)}{V_{IN}(s)} = \frac{N(s)}{D(s)}, D(s) = s^2 + \frac{s\omega_0}{Q} + \omega_0^2$$

$$N_{HP}(s) = s^2 H_{OHP}, N_{BP}(s) = \frac{-s\omega_0 H_{OHP}}{Q}, N_{LP} = \omega_0^2 H_{OLP}.$$

$$f_0 = \frac{1}{2\pi} \sqrt{\frac{R_6}{R_5} \sqrt{\frac{1}{t_1 t_2}}}, t_1 = R_1 C_1, Q = \left(\frac{1 + R_4/R_3 + R_4/R_0}{1 + R_6/R_5} \right) \left(\frac{R_6 t_1}{R_5 t_2} \right)^{1/2}$$

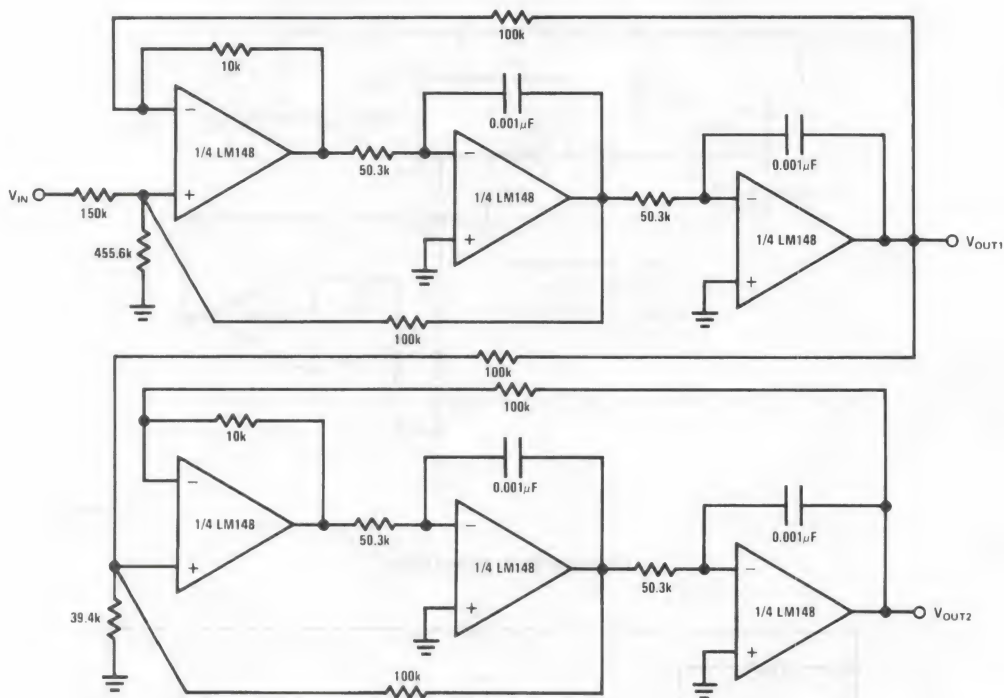

$$f_{NOTCH} = \frac{1}{2\pi} \left(\frac{R_H}{R_L t_1 t_2} \right)^{1/2}, H_{OHP} = \frac{1 + R_6/R_5}{1 + R_3/R_0 + R_3/R_4}, H_{OHP} = \frac{1 + R_4/R_3 + R_4/R_0}{1 + R_3/R_0 + R_3/R_4}$$

$$H_{OLP} = \frac{1 + R_5/R_6}{1 + R_3/R_0 + R_3/R_4}$$

TL/H/7786-11

Typical Applications—LM148 (Continued)

A 1 kHz 4 Pole Butterworth

TL/H/7786-12

Use general equations, and tune each section separately

$Q_{1stSECTION} = 0.541$, $Q_{2ndSECTION} = 1.306$

The response should have 0 dB peaking

A 3 Amplifier Bi-Quad Notch Filter

TL/H/7786-13

$$Q = \sqrt{\frac{R8}{R7}} \times \frac{R1C1}{\sqrt{R3C2R2C1}}, \quad f_o = \frac{1}{2\pi} \sqrt{\frac{R8}{R7}} \times \frac{1}{\sqrt{R2R3C1C2}}, \quad f_{NOTCH} = \frac{1}{2\pi} \sqrt{\frac{R6}{R3R5R7C1C2}}$$

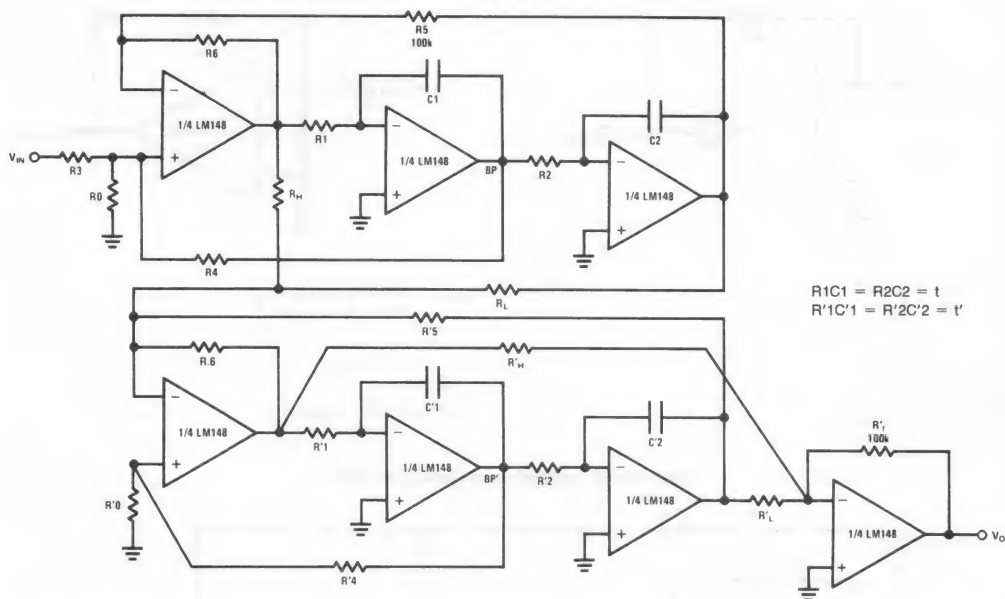

Necessary condition for notch: $\frac{1}{R6} = \frac{R1}{R4R7}$

Ex: $f_{NOTCH} = 3 \text{ kHz}$, $Q = 5$, $R1 = 270k$, $R2 = R3 = 20k$, $R4 = 27k$, $R5 = 20k$, $R6 = R8 = 10k$, $R7 = 100k$, $C1 = C2 = 0.001 \mu F$

Better noise performance than the state-space approach.

Typical Applications—LM148 (Continued)

A 4th Order 1 kHz Elliptic Filter (4 Poles, 4 Zeros)

TL/H/7786-14

$f_C = 1 \text{ kHz}$, $f_S = 2 \text{ kHz}$, $f_P = 0.543$, $f_Z = 2.14$, $Q = 0.841$, $f'_P = 0.987$, $f'_Z = 4.92$, $Q' = 4.403$, normalized to ripple BW

$$f_P = \frac{1}{2\pi} \sqrt{\frac{R_6}{R_5}} \times \frac{1}{t}, f_Z = \frac{1}{2\pi} \sqrt{\frac{R_H}{R_L}} \times \frac{1}{t}, Q = \left(\frac{1 + R_4/R_3 + R_4/R_0}{1 + R_6/R_5} \right) \times \sqrt{\frac{R_6}{R_5}}, Q' = \sqrt{\frac{R'_6}{R_5}} \frac{1 + R'_4/R'_0}{1 + R'_6/R'_5 + R'_6/R'_P}$$

$$R_P = \frac{R_H R_L}{R_H + R_L}$$

Use the BP outputs to tune Q , Q' , tune the 2 sections separately

$R_1 = R_2 = 92.6k$, $R_3 = R_4 = R_5 = 100k$, $R_6 = 10k$, $R_0 = 107.8k$, $R_L = 100k$, $R_H = 155.1k$,

$R'_1 = R'_2 = 50.9k$, $R'_4 = R'_5 = 100k$, $R'_6 = 10k$, $R'_0 = 5.78k$, $R'_L = 100k$, $R'_H = 248.12k$, $R'_f = 100k$. All capacitors are $0.001 \mu F$.

TL/H/7786-15

Typical Applications—LM149

Minimum Gain to Insure LM149 Stability

TL/H/7786-16

$$A_{CL(s)} = \frac{V_{OUT}}{V_{IN}} = \frac{-4}{\left(1 + \frac{5}{A_{OL(s)}}\right)} \approx -4$$

$$V_O \Big|_{V_{IN}=0} \approx \pm 5 V_{OS}$$

Power BW = 40 kHz

Small Signal BW = G BW/5

The LM149 as a Unity Gain Inverter

TL/H/7786-17

$$A_{CL(s)} = \frac{V_{OUT}}{V_{IN}} = \left(\frac{-1}{1 + \frac{6}{A_{OL(s)}}} \right) \approx -1$$

$$V_O \Big|_{V_{IN}=0} \approx \pm 5 V_{OS}$$

Small Signal BW = G BW/5

Non-inverting-Integrator Bandpass Filter

TL/H/7786-18

For stability purposes: $R7 = R6/4$, $10R6 = R5$, $C_C = 10C$

$$f_0 = \frac{1}{2\pi} \sqrt{\frac{R5}{R6}} \times \frac{1}{RC}, Q = \frac{R_Q}{R} \sqrt{\frac{R5}{R6}}, H_{0BP} = \frac{R_Q}{R_{IN}}$$

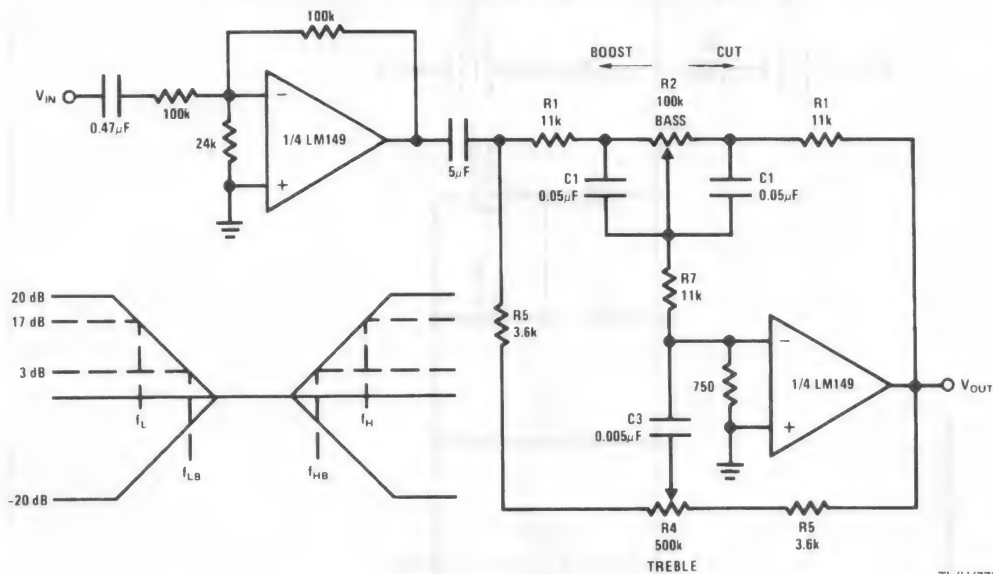

$$f_0(\text{MAX}), Q_{\text{MAX}} = 20 \text{ kHz}, 10$$

Better Q sensitivity with respect to open loop gain variations than the state variable filter.

 $R7, C_C$ added for compensation

Typical Applications—LM149 (Continued)

Active Tone Control with Full Output Swing (No Slew Limiting at 20 kHz)

TL/H/7786-19

 $V_S = \pm 15V, V_{OUT(MAX)} = 9.1 V_{RMS}$
 $f_{MAX} = 20 \text{ kHz}, THD \leq 1\%$

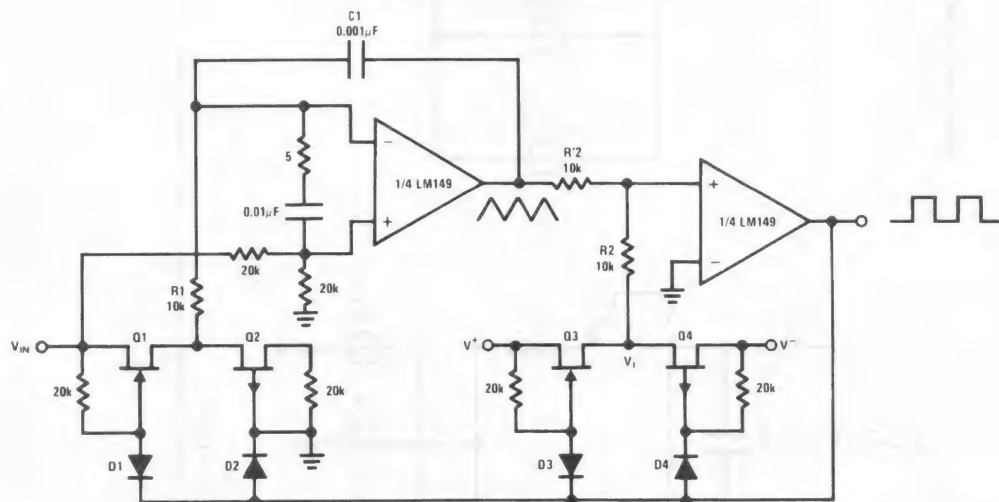

Duplicate the above circuit for stereo

$$f_L = \frac{1}{2\pi R_2 C_1}, f_{LB} = \frac{1}{2\pi R_1 C_1}$$

$$f_H = \frac{1}{2\pi R_5 C_3}, f_{HB} = \frac{1}{2\pi (R_1 + 2R_7) C_3}$$

Max Bass Gain $\approx (R_1 + R_2)/R_1$ Max Treble Gain $\approx (R_1 + 2R_7)/R_5$ as shown: $f_L \approx 32 \text{ Hz}, f_{LB} \approx 320 \text{ Hz}$ $f_H \approx 11 \text{ kHz}, f_{HB} \approx 1.1 \text{ Hz}$

Triangular Squarewave Generator

TL/H/7786-20

$$f = \frac{K \times V_{IN}}{8V^+ C_1 R_1}, K = R_2/R'_2, \frac{2V_I}{K} \leq 25V, V^+ = V^-, V_S = \pm 15V$$

Use LM125 for $\pm 15V$ supply

The circuit can be used as a low frequency V/F for process control.

Q1, Q3: KE4393, Q2, Q4: P1087E, D1-D4 = 1N914

Typical Simulation

LM148, LM149, LM741 Macromodel for Computer Simulation

TL/H/7786-21

$\beta_{01} = 112$ $I_S = 8 \times 10^{-16}$

$\beta_{02} = 144$ $*C2 = 6 \text{ pF}$ for LM149

LM158/LM258/LM358, LM158A/LM258A/LM358A, LM2904 Low Power Dual Operational Amplifiers

General Description

The LM158 series consists of two independent, high gain, internally frequency compensated operational amplifiers which were designed specifically to operate from a single power supply over a wide range of voltages. Operation from split power supplies is also possible and the low power supply current drain is independent of the magnitude of the power supply voltage.

Application areas include transducer amplifiers, dc gain blocks and all the conventional op amp circuits which now can be more easily implemented in single power supply systems. For example, the LM158 series can be directly operated off of the standard $+5 V_{DC}$ power supply voltage which is used in digital systems and will easily provide the required interface electronics without requiring the additional $\pm 15 V_{DC}$ power supplies.

Unique Characteristics

- In the linear mode the input common-mode voltage range includes ground and the output voltage can also swing to ground, even though operated from only a single power supply voltage.
- The unity gain cross frequency is temperature compensated.
- The input bias current is also temperature compensated.

Advantages

- Eliminates need for dual supplies
- Two internally compensated op amps in a single package

- Allows directly sensing near GND and V_{OUT} also goes to GND
- Compatible with all forms of logic
- Power drain suitable for battery operation
- Pin-out same as LM1558/LM1458 dual operational amplifier

Features

- Internally frequency compensated for unity gain
- Large dc voltage gain 100 dB
- Wide bandwidth (unity gain) 1 MHz (temperature compensated)
- Wide power supply range:
 - Single supply $3 V_{DC}$ to $32 V_{DC}$
 - or dual supplies $\pm 1.5 V_{DC}$ to $\pm 16 V_{DC}$
- Very low supply current drain ($500 \mu A$)—essentially independent of supply voltage (1 mW/op amp at $+5 V_{DC}$)
- Low input biasing current (temperature compensated) 45 nA_{DC}
- Low input offset voltage and offset current 2 mV_{DC} 5 nA_{DC}
- Input common-mode voltage range includes ground
- Differential input voltage range equal to the power supply voltage
- Large output voltage swing $0 V_{DC}$ to $V^+ - 1.5 V_{DC}$

Note 1: For operating at high temperatures, the LM358/LM358A, LM2904 must be derated based on a $+125^\circ\text{C}$ maximum junction temperature and a thermal resistance of $120^\circ\text{C}/\text{W}$ which applies for the device soldered in a printed circuit board, operating in a still air ambient. The LM258/LM258A and LM158/LM158A can be derated based on a $+150^\circ\text{C}$ maximum junction temperature. The dissipation is the total of both amplifiers—use external resistors, where possible, to allow the amplifier to saturate or to reduce the power which is dissipated in the integrated circuit.

Note 2: Short circuits from the output to V^+ can cause excessive heating and eventual destruction. When considering short circuits can exceed the power dissipation ratings and cause eventual destruction. Destructive dissipation can result from simultaneous shorts on all amplifiers. V^+ . At values of supply voltage in excess of $+15 V_{DC}$, continuous short-circuits can exceed the power dissipation ratings and cause eventual destruction.

Note 3: This input current will only exist when the voltage at any of the input leads is driven negative. It is due to the collector-base junction of the input PNP transistors becoming forward biased and thereby acting as input diode clamps. In addition to this diode action, there is also lateral NPN parasitic transistor action on the IC chip. This transistor action can cause the output voltages of the op amps to go to the V^+ voltage level (or to ground for a large overdrive) for the time duration that an input is driven negative. This is not destructive and normal output states will re-establish when the input voltage, which was negative, again returns to a value greater than $-0.3 V_{DC}$ (at 25°C).

Note 4: These specifications are limited to $-55^\circ\text{C} \leq T_A \leq +125^\circ\text{C}$ for the LM158/LM158A. With the LM258/LM258A, all temperature specifications are limited to $-25^\circ\text{C} \leq T_A \leq +85^\circ\text{C}$, the LM358/LM358A temperature specifications are limited to $0^\circ\text{C} \leq T_A \leq +70^\circ\text{C}$, and the LM2904 specifications are limited to $-40^\circ\text{C} \leq T_A \leq +85^\circ\text{C}$.

Note 5: $V_{IO} = 1.4 V_{DC}$, $R_S = 0\Omega$ with V^+ from $5 V_{DC}$ to $30 V_{DC}$; and over the full input common-mode range ($0 V_{DC}$ to $V^+ - 1.5 V_{DC}$) at 25°C . For LM2904, V^+ from $5 V_{DC}$ to $26 V_{DC}$.

Note 6: The direction of the input current is out of the IC due to the PNP input stage. This current is essentially constant, independent of the state of the output so no loading change exists on the input lines.

Note 7: The input common-mode voltage of either input signal voltage should not be allowed to go negative by more than $0.3V$ (at 25°C). The upper end of the common-mode voltage range is $V^+ - 1.5V$ (at 25°C), but either or both inputs can go to $+32 V_{DC}$ without damage ($+26 V_{DC}$ for LM2904), independent of the magnitude of V^+ .

Note 8: Due to proximity of external components, insure that coupling is not originating via stray capacitance between these external parts. This typically can be detected as this type of capacitance increases at higher frequencies.

Note 9: Refer to RETS158AX for LM158A military specifications and to RETS158X for LM158 military specifications.

Typical Performance Characteristics

Typical Performance Characteristics (Continued) (LM2902 only)

TL/H/7787-5

Application Hints

The LM158 series are op amps which operate with only a single power supply voltage, have true-differential inputs, and remain in the linear mode with an input common-mode voltage of 0 V_{DC} . These amplifiers operate over a wide range of power supply voltage with little change in performance characteristics. At 25°C amplifier operation is possible down to a minimum supply voltage of 2.3 V_{DC} .

Precautions should be taken to insure that the power supply for the integrated circuit never becomes reversed in polarity or that the unit is not inadvertently installed backwards in a test socket as an unlimited current surge through the resulting forward diode within the IC could cause fusing of the internal conductors and result in a destroyed unit.

Large differential input voltages can be easily accommodated and, as input differential voltage protection diodes are not needed, no large input currents result from large differential input voltages. The differential input voltage may be larger than V^+ without damaging the device. Protection should be provided to prevent the input voltages from going negative more than $-0.3 V_{DC}$ (at 25°C). An input clamp diode with a resistor to the IC input terminal can be used.

To reduce the power supply current drain, the amplifiers have a class A output stage for small signal levels which converts to class B in a large signal mode. This allows the amplifiers to both source and sink large output currents. Therefore both NPN and PNP external current boost transistors can be used to extend the power capability of the basic amplifiers. The output voltage needs to raise approximately 1 diode drop above ground to bias the on-chip vertical PNP transistor for output current sinking applications.

For ac applications, where the load is capacitively coupled to the output of the amplifier, a resistor should be used, from the output of the amplifier to ground to increase the class A bias current and prevent crossover distortion. Where the load is directly coupled, as in dc applications, there is no crossover distortion.

Capacitive loads which are applied directly to the output of the amplifier reduce the loop stability margin. Values of 50 pF can be accommodated using the worst-case non-inverting unity gain connection. Large closed loop gains or resistive isolation should be used if larger load capacitance must be driven by the amplifier.

The bias network of the LM158 establishes a drain current which is independent of the magnitude of the power supply voltage over the range of 3 V_{DC} to 30 V_{DC} .

Output short circuits either to ground or to the positive power supply should be of short time duration. Units can be destroyed, not as a result of the short circuit current causing metal fusing, but rather due to the large increase in IC chip dissipation which will cause eventual failure due to excessive junction temperatures. Putting direct short-circuits on more than one amplifier at a time will increase the total IC power dissipation to destructive levels, if not properly protected with external dissipation limiting resistors in series with the output leads of the amplifiers. The larger value of output source current which is available at 25°C provides a larger output current capability at elevated temperatures (see typical performance characteristics) than a standard IC op amp.

The circuits presented in the section on typical applications emphasize operation on only a single power supply voltage. If complementary power supplies are available, all of the standard op amp circuits can be used. In general, introducing a pseudo-ground (a bias voltage reference of $V^+ / 2$) will allow operation above and below this value in single power supply systems. Many application circuits are shown which take advantage of the wide input common-mode voltage range which includes ground. In most cases, input biasing is not required and input voltages which range to ground can easily be accommodated.

LM192/LM392, LM2924 Low Power Operational Amplifier/Voltage Comparator

General Description

The LM192 series consists of 2 independent building block circuits. One is a high gain, internally frequency compensated operational amplifier, and the other is a precision voltage comparator. Both the operational amplifier and the voltage comparator have been specifically designed to operate from a single power supply over a wide range of voltages. Both circuits have input stages which will common-mode input down to ground when operating from a single power supply. Operation from split power supplies is also possible and the low power supply current is independent of the magnitude of the supply voltage.

Application areas include transducer amplifier with pulse shaper, DC gain block with level detector, VCO, as well as all conventional operational amplifier or voltage comparator circuits. Both circuits can be operated directly from the standard 5 V_{DC} power supply voltage used in digital systems, and the output of the comparator will interface directly with either TTL or CMOS logic. In addition, the low power drain makes the LM192 extremely useful in the design of portable equipment.

Advantages

- Eliminates need for dual power supplies
- An internally compensated op amp and a precision comparator in the same package
- Allows sensing at or near ground
- Power drain suitable for battery operation
- Pin-out is the same as both the LM158 dual op amp and the LM193 dual comparator

Features

- Wide power supply voltage range
 - Single supply 3V to 32V
 - Dual supply $\pm 1.5V$ to $\pm 16V$
- Low supply current drain—essentially independent of supply voltage 600 μA
- Low input biasing current 50 nA
- Low input offset voltage 2 mV
- Low input offset current 5 nA
- Input common-mode voltage range includes ground
- Differential input voltage range equal to the power supply voltage

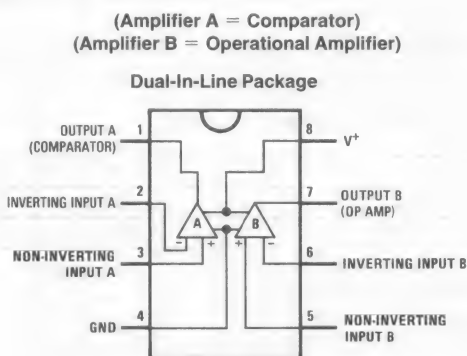

ADDITIONAL OP AMP FEATURES

- Internally frequency compensated for unity gain
- Large DC voltage gain 100 dB
- Wide bandwidth (unity gain) 1 MHz
- Large output voltage swing 0V to V⁺ - 1.5V

ADDITIONAL COMPARATOR FEATURES

- Low output saturation voltage 250 mV at 4 mA
- Output voltage compatible with all types of logic systems

Note 1: For operating at temperatures above 25°C , the LM392N and the LM2924N must be derated based on a 125°C maximum junction temperature and a thermal resistance of $122^\circ\text{C}/\text{W}$ which applies for the device soldered in a printed circuit board, operating in still air ambient. The LM192H/LM392H must be derated based on a 150°C maximum junction temperature and a thermal resistance of $184^\circ\text{C}/\text{W}$. The dissipation is the total of both amplifiers—use external resistors, where possible, to allow the amplifier to saturate or to reduce the power which is dissipated in the integrated circuit.

Note 2: Short circuits from the output to V^+ can cause excessive heating and eventual destruction. When considering short circuits to ground, the maximum output current is approximately 40 mA for the op amp and 30 mA for the comparator independent of the magnitude of V^+ . At values of supply voltage in excess of 15V, continuous short circuits can exceed the power dissipation ratings and cause eventual destruction.

Note 3: This input current will only exist when the voltage at any of the input leads is driven negative. It is due to the collector-base junction of the input PNP transistors becoming forward biased and thereby acting as input diode clamps. In addition to this diode action, there is also lateral NPN parasitic transistor action on the IC chip. This transistor action can cause the output voltages of the amplifiers to go to the V^+ voltage level (or to ground for a large overdrive) for the time duration that an input is driven negative. This is not destructive and normal output states will re-establish when the input voltage, which was negative, again returns to a value greater than -0.3V (at 25°C).

Note 4: These specifications apply for $V^+ = 5\text{V}$ and $-55^\circ\text{C} \leq T_A \leq +125^\circ\text{C}$, unless otherwise stated. For the LM392, temperature specifications are limited to $0^\circ\text{C} \leq T_A \leq +70^\circ\text{C}$ and the LM2924 temperature specifications are limited to $-40^\circ\text{C} \leq T_A \leq +85^\circ\text{C}$.

Note 5: At output switch point, $V_O \approx 1.4\text{V}$, $R_S = 0\Omega$ with V^+ from 5V to 30V; and over the full input common-mode range (0V to $V^+ - 1.5\text{V}$).

Note 6: The direction of the input current is out of the IC due to the PNP input stage. This current is essentially constant, independent of the state of the output so no loading change exists on the input lines.

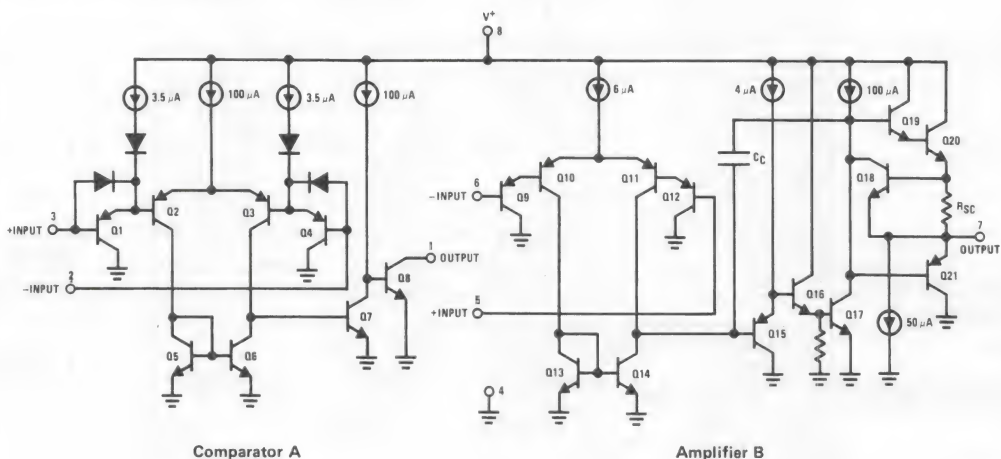

Note 7: The input common-mode voltage or either input signal voltage should not be allowed to go negative by more than 0.3V. The upper end of the common-mode voltage range is $V^+ - 1.5\text{V}$, but either or both inputs can go to 32V without damage (26V for LM2924).

Note 8: Due to proximity of external components, insure that coupling is not originating via the stray capacitance between these external parts. This typically can be detected as this type of capacitive increases at higher frequencies.

Note 9: Positive excursions of input voltage may exceed the power supply level. As long as the other input voltage remains within the common-mode range, the comparator will provide a proper output state. The input voltage to the op amp should not exceed the power supply level. The input voltage state must not be less than -0.3V (or 0.3V below the magnitude of the negative power supply, if used) on either amplifier.

Note 10: The response time specified is for a 100 mV input step with 5 mV overdrive. For larger overdrive signals 300 ns can be obtained.

Application Hints

Please refer to the application hints section of the LM193 and the LM158 datasheets.

LM359 Dual, High Speed, Programmable, Current Mode (Norton) Amplifiers

General Description

The LM359 consists of two current differencing (Norton) input amplifiers. Design emphasis has been placed on obtaining high frequency performance and providing user programmable amplifier operating characteristics. Each amplifier is broadbanded to provide a high gain bandwidth product, fast slew rate and stable operation for an inverting closed loop gain of 10 or greater. Pins for additional external frequency compensation are provided. The amplifiers are designed to operate from a single supply and can accommodate input common-mode voltages greater than the supply.

Applications

- General purpose video amplifiers
- High frequency, high Q active filters
- Photo-diode amplifiers
- Wide frequency range waveform generation circuits
- All LM3900 AC applications work to much higher frequencies

Features

- User programmable gain bandwidth product, slew rate, input bias current, output stage biasing current and total device power dissipation
- High gain bandwidth product ($I_{SET} = 0.5 \text{ mA}$)
400 MHz for $A_V = 10$ to 100
30 MHz for $A_V = 1$
- High slew rate ($I_{SET} = 0.5 \text{ mA}$)
60 V/ μs for $A_V = 10$ to 100
30 V/ μs for $A_V = 1$
- Current differencing inputs allow high common-mode input voltages
- Operates from a single 5V to 22V supply
- Large inverting amplifier output swing, 2 mV to $V_{CC} - 2V$
- Low spot noise, 6 nV/ $\sqrt{\text{Hz}}$, for $f > 1 \text{ kHz}$

Typical Application

TL/H/7788-1

- $A_V = 20 \text{ dB}$
- $-3 \text{ dB bandwidth} = 2.5 \text{ Hz to } 25 \text{ MHz}$
- Differential phase error $< 1^\circ$ at 3.58 MHz
- Differential gain error $< 0.5\%$ at 3.58 MHz

Typical Performance Characteristics (Continued)

Application Hints

The LM359 consists of two wide bandwidth, decompensated current differencing (Norton) amplifiers. Although similar in operation to the original LM3900, design emphasis for these amplifiers has been placed on obtaining much higher frequency performance as illustrated in Figure 1.

This significant improvement in frequency response is the result of using a common-emitter/common-base (cascode) gain stage which is typical in many discrete and integrated video and RF circuit designs. Another versatile aspect of these amplifiers is the ability to externally program many internal amplifier parameters to suit the requirements of a wide variety of applications in which this type of amplifier can be used.

FIGURE 1

TL/H/7788-6

Application Hints (Continued)

DC BIASING

The LM359 is intended for single supply voltage operation which requires DC biasing of the output. The current mirror circuitry which provides the non-inverting input for the amplifier also facilitates DC biasing the output. The basic operation of this current mirror is that the current (both DC and AC) flowing into the non-inverting input will force an equal amount of current to flow into the inverting input. The mirror gain (A_i) specification is the measure of how closely these two currents match. For more details see National Application Note AN-72.

DC biasing of the output is accomplished by establishing a reference DC current into the (+) input, $I_{IN}(+)$, and requiring the output to provide the (-) input current. This forces the output DC level to be whatever value necessary (within the output voltage swing of the amplifier) to provide this DC reference current, Figure 2.

FIGURE 2

The DC input voltage at each input is a transistor V_{BE} ($\approx 0.6 V_{DC}$) and must be considered for DC biasing. For most applications, the supply voltage, V^+ , is suitable and convenient for establishing $I_{IN}(+)$. The inverting input bias current, $I_b(-)$, is a direct function of the programmable input stage current (see current programmability section) and to obtain predictable output DC biasing set $I_{IN}(+) \geq 10 I_b(-)$. The following figures illustrate typical biasing schemes for AC amplifiers using the LM359:

FIGURE 3. Biasing an Inverting AC Amplifier

FIGURE 4. Biasing a Non-Inverting AC Amplifier

FIGURE 5. nV_{BE} Biasing

The nV_{BE} biasing configuration is most useful for low noise applications where a reduced input impedance can be accommodated (see typical applications section).

OPERATING CURRENT PROGRAMMABILITY (I_{SET})

The input bias current, slew rate, gain bandwidth product, output drive capability and total device power consumption of both amplifiers can be simultaneously controlled and optimized via the two programming pins $I_{SET}(OUT)$ and $I_{SET}(IN)$.

$I_{SET}(OUT)$

The output set current ($I_{SET}(OUT)$) is equal to the amount of current sourced from pin 1 and establishes the class A biasing current for the Darlington emitter follower output stage. Using a single resistor from pin 1 to ground, as shown in Figure 6, this current is equal to:

FIGURE 6. Establishing the Output Set Current

Application Hints (Continued)

The output set current can be adjusted to optimize the amount of current the output of the amplifier can sink to drive load capacitance and for loads connected to V^+ . The maximum output sinking current is approximately 10 times $I_{SET(OUT)}$. This set current is best used to reduce the total device supply current if the amplifiers are not required to drive small load impedances.

$I_{SET(IN)}$

The input set current $I_{SET(IN)}$ is equal to the current flowing into pin 8. A resistor from pin 8 to V^+ sets this current to be:

TL/H/7788-12

FIGURE 7. Establishing the Input Set Current

$I_{SET(IN)}$ is most significant in controlling the AC characteristics of the LM359 as it directly sets the total input stage current of the amplifiers which determines the maximum slew rate, the frequency of the open loop dominant pole, the input resistance of the $(-)$ input and the biasing current $I_{b(-)}$. All of these parameters are significant in wide band amplifier design. The input stage current is approximately 3 times $I_{SET(IN)}$ and by using this relationship the following first order approximations for these AC parameters are:

$$S_{r(MAX)} = \text{max slew rate} \approx \frac{3 I_{SET(IN)} (10^{-6})}{C_{comp}} (V/\mu s)$$

$$\text{frequency of dominant pole} \approx \frac{3 I_{SET(IN)}}{2\pi C_{comp} A_{VOL} (0.026V)} (\text{Hz})$$

$$\text{input resistance} = \beta r_e \approx \frac{150 (0.026V)}{3 I_{SET(IN)}} (\Omega)$$

where C_{comp} is the total capacitance from the compensation pin (pin 3 or pin 13) to ground, A_{VOL} is the low frequency open loop voltage gain in V/V and an ambient tempera-

ture of 25°C is assumed ($KT/q = 26 \text{ mV}$ and $\beta_{typ} = 150$). $I_{SET(IN)}$ also controls the DC input bias current by the expression:

$$I_{b(-)} = \frac{3I_{SET}}{\beta} \approx \frac{I_{SET}}{50} \text{ for NPN } \beta = 150$$

which is important for DC biasing considerations.

The total device supply current (for both amplifiers) is also a direct function of the set currents and can be approximated by:

$$I_{supply} \approx 27 \times I_{SET(OUT)} + 11 \times I_{SET(IN)}$$

with each set current programmed by individual resistors.

PROGRAMMING WITH A SINGLE RESISTOR

Operating current programming may also be accomplished using only one resistor by letting $I_{SET(IN)}$ equal $I_{SET(OUT)}$. The programming current is now referred to as I_{SET} and it is created by connecting a resistor from pin 1 to pin 8 (Figure 8).

$$I_{SET} = \frac{V^+ - 2V_{BE}}{R_{SET} + 1 \text{ k}\Omega} \text{ where } V_{BE} \approx 0.6V$$

TL/H/7788-13

$$I_{SET(IN)} = I_{SET(OUT)} = I_{SET}$$

FIGURE 8. Single Resistor Programming of I_{SET}

This configuration does not affect any of the internal set current dependent parameters differently than previously discussed except the total supply current which is now equal to:

$$I_{supply} \approx 37 \times I_{SET}$$

Care must be taken when using resistors to program the set current to prevent significantly increasing the supply voltage above the value used to determine the set current. This would cause an increase in total supply current due to the resulting increase in set current and the maximum device power dissipation could be exceeded. The set resistor value(s) should be adjusted for the new supply voltage.

Application Hints (Continued)

One method to avoid this is to use an adjustable current source which has voltage compliance to generate the set current as shown in *Figure 9*.

FIGURE 9. Current Source Programming of I_{SET}

This circuit allows I_{SET} to remain constant over the entire supply voltage range of the LM359 which also improves power supply ripple rejection as illustrated in the Typical Performance Characteristics. It should be noted, however, that the current through the LM334 as shown will change linearly with temperature but this can be compensated for (see LM334 data sheet).

Pin 1 must never be shorted to ground or pin 8 never shorted to V^+ without limiting the current to 2 mA or less to prevent catastrophic device failure.

CONSIDERATIONS FOR HIGH FREQUENCY OPERATION

The LM359 is intended for use in relatively high frequency applications and many factors external to the amplifier itself must be considered. Minimization of stray capacitances and their effect on circuit operation are the primary requirements. The following list contains some general guidelines to help accomplish this end:

1. Keep the leads of all external components as short as possible.
2. Place components conducting signal current from the output of an amplifier away from that amplifier's non-inverting input.
3. Use reasonably low value resistances for gain setting and biasing.
4. Use of a ground plane is helpful in providing a shielding effect between the inputs and from input to output. Avoid using vector boards.
5. Use a single-point ground and single-point supply distribution to minimize crosstalk. Always connect the two grounds (one from each amplifier) together.
6. Avoid use of long wires ($> 2''$) but if necessary, use shielded wire.
7. Bypass the supply close to the device with a low inductance, low value capacitor (typically a $0.01 \mu\text{F}$ ceramic) to create a good high frequency ground. If long supply leads are unavoidable, a small resistor ($\sim 10\Omega$) in series with the bypass capacitor may be needed and using shielded wire for the supply leads is also recommended.

COMPENSATION

The LM359 is internally compensated for stability with closed loop inverting gains of 10 or more. For an inverting gain of less than 10 and all non-inverting amplifiers (the amplifier always has 100% negative current feedback regardless of the gain in the non-inverting configuration) some external frequency compensation is required because the stray capacitance to ground from the ($-$) input and the feedback resistor add additional lagging phase within the feedback loop. The value of the input capacitance will typically be in the range of 6 pF to 10 pF for a reasonably constructed circuit board. When using a feedback resistance of $30 \text{ k}\Omega$ or less, the best method of compensation, without sacrificing slew rate, is to add a lead capacitor in parallel with the feedback resistor with a value on the order of 1 pF to 5 pF as shown in *Figure 10*.

FIGURE 10. Best Method of Compensation

Another method of compensation is to increase the effective value of the internal compensation capacitor by adding capacitance from the COMP pin of an amplifier to ground. An external 20 pF capacitor will generally compensate for all gain settings but will also reduce the gain bandwidth product and the slew rate. These same results can also be obtained by reducing $I_{SET(N)}$ if the full capabilities of the amplifier are not required. This method is termed over-compensation.

Another area of concern from a stability standpoint is that of capacitive loading. The amplifier will generally drive capacitive loads up to 100 pF without oscillation problems. Any larger C loads can be isolated from the output as shown in *Figure 11*. Over-compensation of the amplifier can also be used if the corresponding reduction of the GBW product can be afforded.

FIGURE 11. Isolating Large Capacitive Loads

Application Hints (Continued)

In most applications using the LM359, the input signal will be AC coupled so as not to affect the DC biasing of the amplifier. This gives rise to another subtlety of high frequency circuits which is the effective series inductance (ESL) of the coupling capacitor which creates an increase in the impedance of the capacitor at high frequencies and can cause an unexpected gain reduction. Low ESL capacitors like solid tantalum for large values of C and ceramic for smaller values are recommended. A parallel combination of the two types is even better for gain accuracy over a wide frequency range.

AMPLIFIER DESIGN EXAMPLES

The ability of the LM359 to provide gain at frequencies higher than most monolithic amplifiers can provide makes it most useful as a basic broadband amplification stage. The design of standard inverting and non-inverting amplifiers, though different than standard op amp design due to the current differencing inputs, also entail subtle design differences between the two types of amplifiers. These differences will be best illustrated by design examples. For these examples a practical video amplifier with a passband of 8 Hz to 10 MHz and a gain of 20 dB will be used. It will be assumed that the input will come from a 75Ω source and proper signal termination will be considered. The supply voltage is 12 V_{DC} and single resistor programming of the operating current, I_{SET}, will be used for simplicity.

AN INVERTING VIDEO AMPLIFIER

1. Basic circuit configuration:

TL/H/7788-17

2. Determine the required I_{SET} from the characteristic curves for gain bandwidth product.

$$GBW_{MIN} = 10 \times 10 \text{ MHz} = 100 \text{ MHz}$$

For a flat response to 10 MHz a closed loop response to two octaves above 10 MHz (40 MHz) will be sufficient.

$$\text{Actual GBW} = 10 \times 40 \text{ MHz} = 400 \text{ MHz}$$

$$I_{SET} \text{ required} = 0.5 \text{ mA}$$

$$R_{SET} = \frac{V^+ - 2 V_{BE}}{I_{SET}} - 1 \text{ k}\Omega = \frac{10.8 \text{ V}}{0.5 \text{ mA}} - 1 \text{ k}\Omega = 20.6 \text{ k}\Omega$$

3. Determine maximum value for R_f to provide stable DC biasing

$$I_{f(MIN)} \geq 10 \times \frac{3 I_{SET}}{\beta} = 100 \mu\text{A} \text{ minimum DC feedback current}$$

Optimum output DC level for maximum symmetrical swing without clipping is:

$$V_{O(DC(opt))} = \frac{V_{O(MAX)} - V_{O(MIN)}}{2} + V_{O(MIN)} \\ \approx \frac{(V^+ - 3 V_{BE}) - 2 \text{ mV}}{2}$$

$$V_{O(DC(opt))} \approx \frac{12 - 1.8 \text{ V}}{2} = \frac{10.2 \text{ V}}{2} = 5.1 \text{ V}_{DC}$$

R_{f(MAX)} can now be found:

$$R_{f(MAX)} = \frac{V_{O(DC(opt))} - V_{BE(-)}}{I_{f(MIN)}} = \frac{5.1 \text{ V} - 0.6 \text{ V}}{100 \mu\text{A}} = 45 \text{ k}\Omega$$

This value should not be exceeded for predictable DC biasing.

4. Select R_s to be large enough so as not to appreciably load the input termination resistance:

$$R_s \geq 750 \Omega \text{ Let } R_s = 750 \Omega$$

5. Select R_f for appropriate gain:

$$A_V = - \frac{R_f}{R_s} \text{ so; } R_f = 10 R_s = 7.5 \text{ k}\Omega$$

7.5 kΩ is less than the calculated R_{f(MAX)} so DC predictability is insured.

6. Since R_f = 7.5k, for the output to be biased to 5.1 V_{DC}, the reference current I_{N(+)} must be:

$$I_{N(+)} = \frac{5.1 \text{ V} - V_{BE(-)}}{R_f} = \frac{5.1 \text{ V} - 0.6 \text{ V}}{7.5 \text{ k}\Omega} = 600 \mu\text{A}$$

Now R_b can be found by:

$$R_b = \frac{V^+ - V_{BE(+)}}{I_{N(+)}} = \frac{12 - 0.6}{600 \mu\text{A}} = 19 \text{ k}\Omega$$

7. Select C_i to provide the proper gain for the 8 Hz minimum input frequency:

$$C_i \geq \frac{1}{2\pi R_s (f_{low})} = \frac{1}{2\pi (750 \Omega) (8 \text{ Hz})} = 26 \mu\text{F}$$

A larger value of C_i will allow a flat frequency response down to 8 Hz and a 0.01 μF ceramic capacitor in parallel with C_i will maintain high frequency gain accuracy.

8. Test for peaking of the frequency response and add a feedback "lead" capacitor to compensate if necessary.

Application Hints (Continued)

Final Circuit Using Standard 5% Tolerance Resistor Values:

TL/H/7788-18

Circuit Performance:

TL/H/7788-19

$$V_{O(DC)} = 5.1V$$

Differential phase error < 1° for 3.58 MHz f_{IN}

Differential gain error < 0.5% for 3.58 MHz f_{IN}

$f_{-3dB \text{ low}} = 2.5 \text{ Hz}$

A NON-INVERTING VIDEO AMPLIFIER

For this case several design considerations must be dealt with.

- The output voltage (AC and DC) is strictly a function of the size of the feedback resistor and the sum of AC and DC "mirror current" flowing into the (+) input.

- The amplifier always has 100% current feedback so external compensation is required. Add a small (1 pF–5 pF) feedback capacitance to leave the amplifier's open loop response and slew rate unaffected.
- To prevent saturating the mirror stage the total AC and DC current flowing into the amplifier's (+) input should be less than 2 mA.
- The output's maximum negative swing is one diode above ground due to the V_{BE} diode clamp at the (-) input.

DESIGN EXAMPLE:

$e_{IN} = 50 \text{ mV (MAX)}$, $f_{IN} = 10 \text{ MHz (MAX)}$, desired circuit BW = 20 MHz, $A_V = 20 \text{ dB}$, driving source impedance = 75Ω , $V^+ = 12V$.

- Basic circuit configuration:

TL/H/7788-20

- Select I_{SET} to provide adequate amplifier bandwidth so that the closed loop bandwidth will be determined by R_F and C_F . To do this, the set current should program an amplifier open loop gain of at least 20 dB at the desired closed loop bandwidth of the circuit. For this example, an I_{SET} of 0.5 mA will provide 26 dB of open loop gain at 20 MHz which will be sufficient. Using single resistor programming for I_{SET} :

$$R_{SET} = \frac{V^+ - 2V_{BE}}{I_{SET}} - 1 \text{ k}\Omega = 20.6 \text{ k}\Omega$$

- Since the closed loop bandwidth will be determined by

$$R_F \text{ and } C_F \left(f_{-3dB} = \frac{1}{2\pi R_F C_F} \right)$$

Application Hints (Continued)

to obtain a 20 MHz bandwidth, both R_f and C_f should be kept small. It can be assumed that C_f can be in the range of 1 pF to 5 pF for carefully constructed circuit boards to insure stability and allow a flat frequency response. This will limit the value of R_f to be within the range of:

$$\frac{1}{2\pi \cdot 5 \text{ pF} \cdot 20 \text{ MHz}} \leq R_f \leq \frac{1}{2\pi \cdot 1 \text{ pF} \cdot 20 \text{ MHz}}$$

$$\text{or } 1.6 \text{ k}\Omega \leq R_f \leq 7.96 \text{ k}\Omega$$

Also, for a closed loop gain of +10, R_f must be 10 times $R_s + r_e$ where r_e is the mirror diode resistance.

4. So as not to appreciably load the 75 Ω input termination resistance the value of $(R_s + r_e)$ is set to 750 Ω .
5. For $A_v = 10$; R_f is set to 7.5 k Ω .
6. The optimum output DC level for symmetrical AC swing is:

$$V_{oDC(opt)} = \frac{V_{o(MAX)} - V_{o(MIN)}}{2} + V_{o(MIN)}$$

$$= \frac{(12 - 1.8)\text{V} - 0.6\text{V}}{2} + 0.6\text{V} = 5.4 \text{ V}_{DC}$$

7. The DC feedback current must be:

$$I_{FB} = \frac{V_{oDC(opt)} - V_{BE(-)}}{R_f} = \frac{5.4\text{V} - 0.6\text{V}}{7.5\text{k}} = 640 \mu\text{A} = I_{N(+)}$$

DC biasing predictability will be insured because 640 μA is greater than the minimum of $I_{SET}/5$ or 100 μA .

For gain accuracy the total AC and DC mirror current should be less than 2 mA. For this example the maximum AC mirror current will be;

$$\frac{\pm e_{in \text{ peak}}}{R_s + r_e} = \frac{\pm 50 \text{ mV}}{750 \Omega} = \pm 66 \mu\text{A}$$

therefore the total mirror current will be 574 μA to 706 μA which will insure gain accuracy.

8. R_b can now be found:

$$R_b = \frac{V^+ - V_{BE(+)}}{I_{N(+)}} = \frac{12 - 0.6}{640 \mu\text{A}} = 17.8 \text{ k}\Omega$$

9. Since $R_s + r_e$ will be 750 Ω and r_e is fixed by the DC mirror current to be:

$$r_e = \frac{KT}{q I_{N(+)}} = \frac{26 \text{ mV}}{640 \mu\text{A}} \approx 40 \Omega \text{ at } 25^\circ\text{C}$$

R_s must be 750 Ω –40 Ω or 710 Ω which can be a 680 Ω resistor in series with a 30 Ω resistor which are standard 5% tolerance resistor values.

10. As a final design step, C_i must be selected to pass the lower passband frequency corner of 8 Hz for this example.

$$C_i = \frac{1}{2\pi (R_s + r_e) f_{low}} = \frac{1}{2\pi (750 \Omega) (8 \text{ Hz})} = 26.5 \mu\text{F}$$

A larger value may be used and a 0.01 μF ceramic capacitor in parallel with C_i will maintain high frequency gain accuracy.

Final Circuit Using Standard 5% Tolerance Resistor Values

$V_{O(DC)} = 5.4V$
 Differential phase error $< 0.5^\circ$
 Differential gain error $< 2\%$
 $f_{-3\text{ dB low}} = 2.5\text{ Hz}$

GENERAL PRECAUTIONS

The LM359 is designed primarily for single supply operation but split supplies may be used if the negative supply voltage is well regulated as the amplifiers have no negative supply rejection.

The total device power dissipation must always be kept in mind when selecting an operating supply voltage, the programming current, I_{SET} , and the load resistance, particularly when DC coupling the output to a succeeding stage. To prevent damaging the current mirror input diode, the mirror current should always be limited to 10 mA, or less, which is important if the input is susceptible to high voltage transients. The voltage at any of the inputs must not be forced more negative than $-0.7V$ without limiting the current to 10 mA.

The supply voltage must never be reversed to the device; however, plugging the device into a socket backwards would then connect the positive supply voltage to the pin that has no internal connection (pin 5) which may prevent inadvertent device failure

Typical Applications

DC Coupled Inputs

Inverting

TL/H/7788-23

$$V_{O(DC)} = \left[\frac{V^+ - V_{BE}(+)}{R_b} - \frac{V_{IN(DC)} - V_{BE}(-)}{R_s} \right] R_f + V_{BE}(-)$$

$$A_{V(AC)} = \frac{R_f}{R_s}$$

- Eliminates the need for an input coupling capacitor
- Input DC level must be stable and can exceed the supply voltage of the LM359 provided that maximum input currents are not exceeded.

Non-Inverting

TL/H/7788-24

$$V_{O(DC)} = V_{BE}(-) + \frac{(V_{IN(DC)} - V_{BE}(+)) R_f}{R_s}$$

$$A_{V(AC)} = + \frac{R_f}{R_s + r_{e}(+)}$$

Application Hints (Continued)

Noise Reduction using nV_{BE} Biasing

TL/H/7788-25

nV_{BE} Biasing with a Negative Supply

TL/H/7788-26

- R1 and C2 provide additional filtering of the negative biasing supply

Typical Input Referred Noise Performance

TL/H/7788-27

Adding a JFET Input Stage

TL/H/7788-28

- FET input voltage mode op amp
- For $A_V = +1$; $BW = 40$ MHz, $S_r = 60$ V/ μ s; $C_C = 51$ pF
- For $A_V = +11$; $BW = 24$ MHz, $S_r = 130$ V/ μ s; $C_C = 5$ pF
- For $A_V = +100$; $BW = 4.5$ MHz, $S_r = 150$ V/ μ s; $C_C = 2$ pF
- V_{OS} is typically < 25 mV; 100Ω potentiometer allows a V_{OS} adjust range of $\approx \pm 200$ mV
- Inputs must be DC biased for single supply operation

Typical Applications (Continued)

Photo Diode Amplifier

TL/H/7788-29

D1 ~ RCA N-Type Silicon P-I-N Photodiode

- Frequency response of greater than 10 MHz
- If slow rise and fall times can be tolerated the gate on the output can be removed. In this case the rise and the fall time of the LM359 is 40 ns.
- $T_{PDL} = 45 \text{ ns}$, $T_{PDH} = 50 \text{ ns}$ - T²L output

Balanced Line Driver

TL/H/7788-30

$$\text{For } V_{O1} = V_{O2} = \frac{V^+}{2}, \quad \frac{R_3}{R_2} = \frac{V^+ - 2\phi}{2(V^+ - \phi)}, \quad \frac{R_6}{R_5} = \frac{V^+ - 2\phi}{\phi} \text{ where } \phi \approx 0.6V$$

$$A_v = \frac{R_3}{R_1} \left(\frac{R_6}{R_4} + 1 \right)$$

- 1 MHz—3 dB bandwidth with gain of 10 and 0 dbm into 600Ω
- 0.3% distortion at full bandwidth; reduced to 0.05% with bandwidth of 10 kHz
- Will drive $C_L = 1500 \text{ pF}$ with no additional compensation, $\pm 0.01 \mu\text{F}$ with $C_{comp} = 180 \text{ pF}$
- 70 dB signal to noise ratio at 0 dbm into 600Ω, 10 kHz bandwidth

Typical Applications (Continued)

Difference Amplifier

$$V_{O(DC)} = \frac{R_4}{R_3} (V^+ - \phi) \text{ where } \phi = 0.6V$$

LM604A/LM604 4 Channel Mux-Amp

General Description

The LM604 Mux-Amp is an op-amp with four selectable differential inputs, combining the functions of a multiplexer with an op-amp. The LM604 can select, buffer, and amplify one of four different input signals, providing a complete system for multiplexing analog signals. It also has the unique Bi-State output which allows two or more Mux-Amps to be connected together at their outputs to increase the number of multiplexed channels. Channel selection and the Bi-State output are controlled by internal logic that interfaces directly to a microprocessor. Besides these unique features, the LM604 has excellent AC and DC op-amp specifications and is internally compensated.

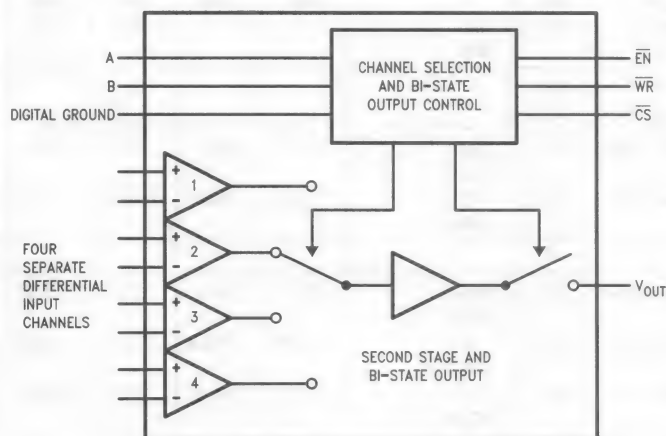

Applications include signal multiplexing and linear circuits that are controlled by digital signals (i.e., programmable gain blocks, filters, and other op-amp circuits).

Features

- Multiplexes four differential input channels to a single op-amp
- Easy to interface to microprocessor, or operates "stand alone"
- Bi-State output: Operates in two states, Active and Disabled. When disabled, it becomes a high impedance.
- Wide operating voltage range

single supply	4V to 32V
split supply	$\pm 2V$ to $\pm 16V$
- Wide input common mode range V^- to $V^+ - 1V$
- Fast channel to channel switching time 5 μs
- Output will drive a 600 Ω load

Functional Description

INPUT CHANNEL SELECTION

The LM604 contains four differential input channels that are selected one at a time. An input is selected by writing its binary code to pins A and B when \overline{CS} and \overline{WR} are a logic 0, see block diagram. The LM604 always has one of its inputs selected. In order to isolate all four channels from the output, the Bi-State output can be disabled.

Figure 5 illustrates how the LM604 switches from one channel to another. The switching begins on the falling edge of \overline{WR} if A and B are valid before \overline{WR} is a logic 0, or when A and B become valid while \overline{WR} is a logic 0. In either case, the channel switching time (t_{SW2}) remains the same. If a channel is to remain selected, its binary code must be valid during the rising edge of \overline{WR} as specified by t_S and t_H .

Channel switching time is specified by t_{SW1} and t_{SW2} as shown in Figure 2. t_{SW1} is the time it takes the output to first reach its new value, and t_{SW2} is the time it takes the output to settle to within 0.1% of its new value. Clearly, t_{SW2} is a more useful parameter for specifying switching time, but it is difficult to test on a production basis. Therefore, t_{SW1} is tested and this allows t_{SW2} to be guaranteed. Channel switching time will vary as a function of how far the output swings to reach its new value. This is shown in Figure 6 where t_{SW2} is plotted as a function of output voltage swing (ΔV_{OUT}).

TL/H/9131-12

$$\Delta V_{OUT} = V_{OUT} (\text{Selected Channel}) - V_{OUT} (\text{Previous Channel})$$

FIGURE 6. t_{SW2} vs ΔV_{OUT}

BI-STATE OUTPUT

The Bi-State output can be either enabled (on) or disabled (off). When disabled, the output becomes a high impedance load that can be driven by another output stage. This allows several Mux-Amps to be connected together at their outputs by having only one output enabled at one time. Thus, several Mux-Amps can be in parallel to the same output to increase the number of multiplexed channels. The Bi-State output is controlled by \overline{EN} when \overline{CS} and \overline{WR} are a logic 0, see block diagram.

When the output is disabled and driven by another output, it behaves like a small capacitive load with a few microamps of leakage current. The data sheet specifies this with the

parameters "Output Capacitance" and "Output Leakage Current". Both parameters vary with temperature, as shown in Figure 7.

TL/H/9131-13

TL/H/9131-14

FIGURE 7. $I_{LEAKAGE}$ and C_{OUT} vs Temperature

Figure 8 illustrates switching between two Mux-Amps that are connected in parallel to the same output. Switching begins on the falling edge of \overline{WR} if the \overline{EN} signals are correctly set before \overline{WR} is a logic 0, or when the \overline{EN} signals become valid while \overline{WR} is a logic 0. The Bi-State output takes less time to become disabled than it does to become enabled, and this insures the outputs are switched in a "break before make" method. If an in output is to remain enabled or disabled after \overline{WR} becomes a logic 1, \overline{EN} must be valid during the rising edge of \overline{WR} as specified by t_S and t_H . Note that when a Mux-Amp has its output enabled, the binary code for the selected input channel must also be written.

Bi-State output enable time (t_{EN1} and t_{EN2}) and disable time (t_{DIS}) are defined in Figure 3. t_{EN1} is the time it takes the output to first reach its enabled value (V_{EN}), and t_{EN2} is the time it takes the output to settle to within 0.1% of V_{EN} . As with channel switching time, t_{EN1} is a tested parameter that allows t_{EN2} to be guaranteed. t_{DIS} is the time it takes the output to become a high impedance. Output enable time will vary according to how far the output swings from V_{DIS} to V_{EN} , and this is plotted in Figure 9.

DIGITAL CONTROL

As mentioned in the previous sections, the input channels and Bi-State output are controlled by logic levels on pins A, B, and \overline{EN} . There are two ways to apply logic levels to these pins. 1) Hardwire \overline{WR} and \overline{CS} directly to digital ground so that the LM604 operates in a "stand alone" mode. This allows input logic levels to directly control the LM604. 2) Write digital signals to A, B, and \overline{EN} as shown in the timing diagrams of Figures 5 and 8. This method is used when the LM604 interfaces to a microprocessor. Note that \overline{CS} and \overline{WR} can occur simultaneously, so set-up and hold times are not required for \overline{CS} . Also, notice that \overline{WR} must remain a logic 1 during the hold time period.

Input logic levels are referenced to a 1.4V threshold voltage, making the LM604 compatible with TTL and CMOS logic. This threshold voltage is referenced to digital ground. The voltage level of digital ground can be as low as V^- (pin 15) and as high as 4V below V^+ (pin 5).

Application Hints

USING MULTIPLE FEEDBACK LOOPS

Each input channel of the LM604 is used as a single op-amp with its own feedback loop. Two examples of this are circuits with multiple inverting gain channels and non-inverting gain channels (Figure 10). These circuits have multiple feedback loops connected to the same output with one feedback loop connected to a selected channel and the others connected to "off" channels. The feedback loop of the selected channel determines the gain of these circuits. The off channel feedback loops affect these circuits in two ways. 1) They create an additional load at the output. 2) Feedback loops for inverting gain channels provide feedthrough paths from the inputs of the off channels to the output.

In Figure 10, the loading affect of multiple feedback loops is given in terms of current flowing through the feedback loops (I_F). In circuits with non-inverting gain channels, I_F is a function of V_{OUT} and the resistance of the feedback loops. In circuits with inverting gain channels, I_F is different for each channel selected because it is also a function of the off channel input voltages. This additional loading must be accounted for when designing Mux-Amp circuits. Otherwise, the output load resistance will be less than anticipated.

TL/H/9131-19

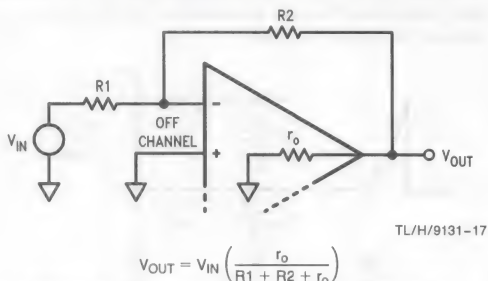

Channel	V_O
1	$V_1 \left(1 + \frac{R_7}{R_8} \right)$
2	$V_2 \left(1 + \frac{R_6}{R_8} \right)$
3	$V_3 \left(1 + \frac{R_5}{R_8} \right)$
4	$V_4 \left(1 + \frac{R_4}{R_8} \right)$

$$I_F = V_O \left(\frac{1}{R_1 + R_2} + \frac{1}{R_3 + R_4} + \frac{1}{R_5 + R_6} + \frac{1}{R_7 + R_8} \right)$$

Multiple Non-Inverting Gain Channels

FIGURE 10. Circuits Using Multiple Inverting and Non-Inverting Gain Channels

Figure 11 illustrates feedthrough in an off inverting gain channel. Feedthrough occurs because the feedback resistors and the Mux-Amp output impedance (r_o) form a voltage divider. This divider allows a portion of the off channel's input signal to appear at the output. The amount of signal that feeds through depends on the ratio of output impedance to feedback loop resistance. Output impedance varies according to Mux-Amp gain (gain of the selected channel) and the frequency of the feedthrough signal. This variation must be considered when calculating feedthrough, and it is plotted in the "Typical Device Characteristics" section.

4	$-V_4 \left(\frac{R_8}{R_7} \right)$	$\frac{V_O}{R_8} + \frac{V_O - V_1}{R_1 + R_2} + \frac{V_O - V_2}{R_3 + R_4} + \frac{V_O - V_3}{R_5 + R_6}$

Multiple Inverting Gain Channels

Application Hints (Continued)

INPUT CHARGE INJECTION

When the Mux-Amp switches channels, charge is injected from the inputs of the selected and previous channels, see *Figure 12*. This causes a positive error voltage at the input of the selected channel and a negative voltage at the previous channel. The amplitude of this error voltage equals Q_{INJ}/C_{IN} , where C_{IN} is the total capacitance at the input and Q_{INJ} is the charge injected. As plotted in *Figure 13*, Q_{INJ} increases proportionally with the difference in voltage between a channel's input common mode voltage and the negative supply. The RC time constant of C_{IN} times resistance seen from the input will determine how long the error voltage remains at the input.

TL/H/9131-20

FIGURE 12. Error Voltage From Input Charge Injection

TL/H/9131-21

FIGURE 13. Q_{INJ} vs $V_{CM} - V^-$

MAXIMUM OUTPUT LOAD CONDITIONS

The Mux-Amp is guaranteed to drive a 600Ω load as specified over its entire operating range. Reducing the load resistance below this value may cause the output to current

limit. It may also cause the junction temperature limit to be exceeded when operating the part near its maximum ambient temperature.

The Mux-Amp is unconditionally stable with as much as 500 pF connected from the output to ground. If the output is required to drive a larger capacitive load, the Mux-Amp may need to operate with at least a gain of 10. Otherwise, it may become unstable when sinking current.

DIGITAL FEEDTHROUGH

When interfacing the Mux-Amp to a microprocessor, pins A, B, \overline{EN} , and \overline{WR} are connected to an address bus where high frequency digital signals are present. The fast edges of these signals can propagate into the Mux-Amp's analog signal path, causing fast transients to appear at the output. To avoid this problem, the following precautions should be taken.

- 1) Analog and digital ground must be kept separate. They can only be connected together back at the power supply or supply bus.
- 2) Bypass capacitors should have low inductance to prevent noise spikes on the voltage supply pins. A ceramic disc capacitor of 0.1 μ F is usually sufficient.
- 3) All lead lengths should be kept short to prevent them from picking up digital signals.

By using these rules, digital signals can be attenuated at the input channels by typically 100 dB.

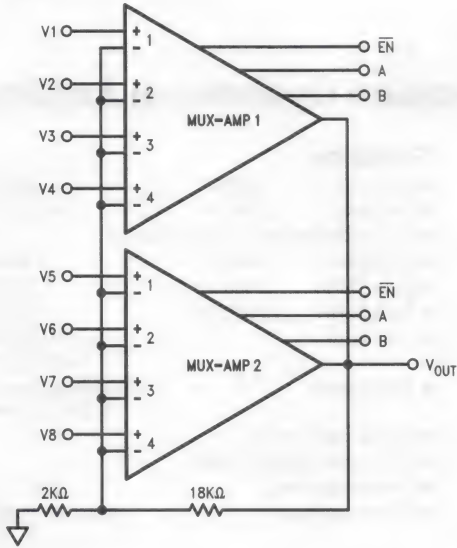

Lab measurements have shown a minimum digital feedthrough signal of 2 mV occurs at the output even when the best layout precautions are taken. This is fine for many applications, but to completely eliminate digital feedthrough, any signals coming directly from the bus must be sent to the Mux-Amp via a Tri-State buffer, see *Figure 14*. This isolates the Mux-Amp's digital pins from the address bus to prevent pin to pin feedthrough. CS can be used to enable the Tri-State buffers when signals are sent to the Mux-Amp from the address bus.

LM607/LM607A/LM607B Precision Operational Amplifier

General Description

The LM607 series of precision operational amplifiers are trimmed at wafer sort to extremely low values of offset voltage. Advanced circuit design and testing techniques allow guaranteed drift specifications as low as $0.3 \mu\text{V}/^\circ\text{C}$ with offsets as low as $25 \mu\text{V}$.

Other input parameters are equally impressive. The typical open loop voltage gain of 5 Million yields extremely low error in high-gain applications. CMRR and PSRR are typically 140 dB.

Using Super-Beta transistors in the front end enables the LM607 to operate at high input stage current while maintaining low values of input bias current (1 nA typ.) This gives the part its low input voltage noise: $6.5 \text{ nV}/\sqrt{\text{Hz}}$.

High operating currents also help give the LM607 its high gain-bandwidth product of 1.8 MHz and slew rate of $0.7\text{V}/\mu\text{s}$. Despite its higher speed, the LM607 draws less supply current than OP-07 types: only 1 mA at $\pm 15\text{V}$ supplies.

Features

- Low V_{OS} LM607A: $25 \mu\text{V}$ max
- Low drift LM607A: $0.3 \mu\text{V}/^\circ\text{C}$ max
- Drift 100% tested: A and B grades
- High gain LM607A: 5 million min
- High CMRR LM607A: 124 dB min
- High PSRR LM607A: 120 dB min
- Low noise LM607A: $6.5 \text{ nV}/\sqrt{\text{Hz}}$ @ 1 kHz
 $9 \text{ nV}/\sqrt{\text{Hz}}$ @ 10 Hz
- High speed 1.8 MHz gain-bandwidth
 $0.7\text{V}/\mu\text{s}$ slew rate
- Low supply current 1 mA
- Wide input common mode $\pm 13\text{V}$
- Wide supply range $\pm 3\text{V}$ to $\pm 18\text{V}$
- Overcompensation Allows driving high C_L

Note 1: All limits guaranteed for $T_J = 25^\circ\text{C}$, $V_{CM} = 0$, $V_O = 0$ and $\pm 15V$ supplies unless otherwise specified. **Boldface limits apply at temperature extremes.**

Note 2: Input offset voltage for A and B grades is tested and guaranteed with the device fully warmed up. See Figure 1 in the Application Hints for test circuit. Warmup drift is typically $3 \mu\text{V}$ settling out in 5 minutes. The LM607C offset voltage is measured by automated test equipment within 200 ms of applying power.

Note 3: Input offset voltage drift is defined as $[V_{OS}(70^\circ\text{C}) - V_{OS}(-5^\circ\text{C})]/75^\circ\text{C}$ for the commercial temperature range. For the military temperature range, the input offset voltage drift is measured from room temperature to both extremes: both $[V_{OS}(25^\circ\text{C}) - V_{OS}(-55^\circ\text{C})]/80^\circ\text{C}$ and $[V_{OS}(125^\circ\text{C}) - V_{OS}(25^\circ\text{C})]/100^\circ\text{C}$.

Note 4: Input offset voltage long term stability refers to the average trend line of V_{OS} vs. time over extended periods of time after the first 30 days of operation. Excluding the initial hour of operation, changes in V_{OS} during the first 30 days are typically $2 \mu\text{V}$.

Note 5: Guaranteed and 100% production tested.

Note 6: Guaranteed but not 100% production tested. These limits are not used to calculate outgoing quality levels.

Note 7: Inputs are protected by back-to-back diodes to prevent zener breakdown of the input transistors. Series limiting resistors have not been included since they degrade noise performance. Excessive current may flow if a differential voltage in excess of $0.7V$ is applied.

Note 8: Power Supply Rejection Ratio is tested by moving both power supplies together from their minimum to maximum values.

Note 9: Typical thermal resistance of the molded package is 95°C/W junction-to-ambient. Typical thermal resistance of the metal can package is 150°C/W junction-to-ambient and 17°C/W junction-to-case.

Application Hints

OFFSET VOLTAGE

Offset voltage of the LM607 is internally trimmed to a very low value. The data sheet V_{OS} specification applies at $T_J = 25^\circ\text{C}$, $V_{CM} = 0$ and $\pm 15V$ supplies. For other conditions, temperature drift, common-mode rejection and power-supply rejection errors must be taken into account.

Although the LM607C is specified as $T_J = 25^\circ\text{C}$, the $3 \mu\text{V}$ typical warmup drift is a small fraction of its $100 \mu\text{V}$ max offset. For the $25 \mu\text{V}$ LM607A and $50 \mu\text{V}$ LM607B grades, the offset voltage is measured fully warmed up with the circuit of Figure 1 approximately 5 minutes after applying power.

To measure V_{OS} with high accuracy, gain must be taken right at the device as shown, otherwise the offset voltage would get swamped out by noise and thermoelectric voltages. Thermocouples occur in the devices, the IC socket and the resistor across the device inputs (R_2), all of which must be held isothermal. Usually best results are obtained by placing the circuit in a box or chamber to minimized air-

flow and employing a long thermal soak time. R_2 should be mounted symmetrically with respect to potential thermal gradients: e.g. *not* perpendicular to the board but instead parallel to the board and the device socket. In addition, R_2 should have low thermal emf. Cermet or nichrome metal film types are acceptable; avoid tin-oxide resistors.

TL/H/8787-3

FIGURE 1. Offset Voltage Test Circuit

OFFSET NULLING

This is usually not required on the LM607 family since its offset voltage is internally trimmed. An offset adjust range of

Application Hints (Continued)

approximately ± 1.5 mV is available using a single 10 or 20 k Ω potentiometer as shown in Figure 2. With these values, the adjustment is relatively linear over the entire range. If a 100 k Ω potentiometer is used, the adjustment becomes very coarse at the extremes (above 700 μ V) but fine in the center, which makes it easier to precisely null the offset. For even more sensitivity, employ a pot in conjunction with two fixed resistors. For example the circuit of Figure 3 has an adjustment range of ± 150 μ V.

TL/H/8787-4

FIGURE 2. Offset Adjust Circuit

TL/H/8787-5

FIGURE 3. Improved Sensitivity Offset Adjust

Because adjusting the offset voltage of an LM607 will alter its offset voltage temperature drift, caution is advised. Every 100 μ V of offset will produce a 0.33 μ V/ $^{\circ}$ C drift component. For this reason the offset adjust potentiometer should not be used to null out a sensor offset if system temperature drift is important; rather a stable voltage reference must be added to the sensor voltage. Offset voltage drift is guaranteed by design for the LM607C either with or without external nulling. The higher precision A and B grades are 100% drift tested and guaranteed without nulling only.

OVERCOMPENSATION

Without any external compensation, the LM607 is stable at unity gain and up to 750 pF load capacitance. It has a slew rate of 0.7V/ μ s and a gain-bandwidth product of 1.8 MHz. If desired, the amplifier may be overcompensated by adding external components as shown in Figure 4. This increases maximum capacitive loading to 0.01 μ F while decreasing

slew rate to 0.13V/ μ s and bandwidth to 200 kHz. If overcompensation is not desired, pin 5 should be left open.

TL/H/8787-6

FIGURE 4. Overcompensation

NOISE

The LM607 achieves lower voltage noise than the OP-07 primarily by operating at higher input stage current. Its superbeta input transistors and trimmed bias-current compensation prevent the bias current from increasing. When measuring spot noise, a circuit as shown in Figure 5 is recommended. The DUT runs at a gain of 100 will not roll off until approximately 15 kHz. Another gain of 100 amplifier following brings total DUT-input-referred gain up to 10,000 to minimize sensitivity to EMI in the environment. When measuring spot noise at 100 Hz, it is recommended that the bandwidth be 20 Hz or less to minimize pickup of 120 Hz, the second harmonic of line frequency.

TL/H/8787-7

FIGURE 5. Spot Noise Test Circuit

The circuit used to measure peak-to-peak noise in the 0.1 to 10 Hz range is shown in Figure 6. The device should be warmed up for about 2 minutes and shielded from air currents to minimize warmup drift and thermoelectric voltages. The test time should be limited to only 10 seconds, as this limits noise contributions below 0.1 Hz, in addition to the single zero rolloff. The measuring equipment must be flat beyond this bandwidth. DC coupling must be employed to ensure this. Certain types of X-Y plotters may not be usable because of severe rolloff above a few Hz.

Application Hints (Continued)

FIGURE 6.0.1 to 10 Hz Noise Test Circuit

Input Overdrive

The LM607's input-protection diodes prevent zener breakdown of the input transistors and the ensuing degradation of input DC parameters. Current limiting resistors have not been included as they would degrade input noise voltage. Input current should be limited to ± 25 mA to avoid potential damage to the IC metallization.

In voltage follower applications, large input voltage steps may be coupled directly to the op amp's output via the protection diodes. If the input and feedback resistances are low in value, the output stage may be driven temporarily into current limit. The resulting output waveform exhibits an initial fast step when the diodes are conducting followed by a slight glitch as the amplifier comes out of current limit before true slewing is observed. For best results, use input and feedback resistors of 2 kΩ each in parallel with 30 pF capacitors. The capacitors eliminate input and feedback poles which respectively cause signal rolloff and instabilities.

LM611 Adjustable Micropower Floating Voltage Reference and Single-Supply Operational Amplifier

General Description

The voltage reference is a three-terminal shunt-type band-gap similar to the adjustable LM185 series, but with improved voltage accuracy. To $\pm 0.4\%$ accuracy by wafer trim. Two resistors program the reference from 1.24V to 6.3V. Operation over a shunt current range of 16 μA to 20 mA, low dynamic impedance, broad capacitive load range, and cathode terminal voltage ranging from a diode-drop below V^- to above V^+ result in easy application.

The operational amplifier is a versatile common-mode-to-the-negative-supply ("single-supply") type similar to the LM124 series, but with improved slew rate, improved power bandwidth, reduced cross-over distortion, and low supply current even while driven beyond swing limits. Lateral PNP input transistors enable low input currents for large differential input voltages and swings above V^+ .

Features (Guaranteed over temperature and supply)

- Low operating current 300 μA (per op amp)
16 μA (ref)
- Large supply voltage range 3V to 36V
- Large output swing (10k load) ($V^- + 1V$) to ($V^+ - 1.8V$)
- Input common-mode range includes V^- to ($V^+ - 1.4V$)
- Op amps match LM124 pin-out
- Wide input differential voltage $\pm 36V$
- Reference voltage adjustable 1.2V to 6.3V
- Reference initial tolerance $\pm 0.4\%$
- Reference temp. coefficient ± 20 ppm/ $^{\circ}\text{C}$
- Reference load capacitance 0 to ∞
- Cost effective

Applications

- Power supplies
- Signal conditioning

LM614 Adjustable Micropower Floating Voltage Reference and Four Single-Supply Operational Amplifiers

General Description

The voltage reference is a three-terminal shunt-type design similar to the adjustable LM185 series, but with improved voltage tolerance and temperature coefficient. It is adjustable from 1.23 to 6.3V and operates over a wide shunt current range of 12 μ A to 20 mA. Trimming provides accuracy to $\pm 1/3\%$. The low dynamic impedance and wide capacitive load range result in easy application.

The four operational amplifiers are versatile single-supply types similar to the LM124 series, but with improved slew rate (0.8V/ μ s typ.) and power bandwidth, reduced cross-over distortion, and low current consumption even while driven beyond swing limits.

Features

- Low operating current 185 μ A (per op amp)
12 μ A (reference)
- Wide supply voltage range 3V to 36V
- Large output swing ($V^- + 0.9V$) to ($V^+ - 1.7V$)
- Input common-mode range includes V^-
- Reference voltage adjustable 1.2V to 6.3V
- Reference initial tolerance $\pm 0.33\%$
- Reference temp coefficient ± 20 PPM/C
- Reference tolerant of capacitive loads

Applications

- Instrumentation
- Switching power supplies
- Battery operated devices

LM675 Power Operational Amplifier

General Description

The LM675 is a monolithic power operational amplifier featuring wide bandwidth and low input offset voltage, making it equally suitable for AC and DC applications.

The LM675 is capable of delivering output currents in excess of 3 amps, operating at supply voltages of up to 60V. The device overload protection consists of both internal current limiting and thermal shutdown. The amplifier is also internally compensated for gains of 10 or greater.

Features

- 3A current capability
- A_{VO} typically 90 dB
- 5.5 MHz gain bandwidth product
- 8 V/ μ s slew rate
- Wide power bandwidth 70 kHz

- 1 mV typical offset voltage
- Short circuit protection
- Thermal protection with parole circuit (100% tested)
- 16V–60V supply range
- Wide common mode range
- Internal output protection diodes
- 90 dB ripple rejection
- Plastic power package TO-220

Applications

- High performance power op amp
- Bridge amplifiers
- Motor speed controls
- Servo amplifiers
- Instrument systems

Application Hints

STABILITY

The LM675 is designed to be stable when operated at a closed-loop gain of 10 or greater, but, as with any other high-current amplifier, the LM675 can be made to oscillate under certain conditions. These usually involve printed circuit board layout or output/input coupling.

When designing a printed circuit board layout, it is important to return the load ground, the output compensation ground, and the low level (feedback and input) grounds to the circuit board ground point through separate paths. Otherwise, large currents flowing along a ground conductor will generate voltages on the conductor which can effectively act as signals at the input, resulting in high frequency oscillation or excessive distortion. It is advisable to keep the output compensation components and the 0.1 μF supply decoupling capacitors as close as possible to the LM675 to reduce the effects of PCB trace resistance and inductance. For the same reason, the ground return paths for these components should be as short as possible.

Occasionally, current in the output leads (which function as antennas) can be coupled through the air to the amplifier input, resulting in high-frequency oscillation. This normally happens when the source impedance is high or the input leads are long. The problem can be eliminated by placing a small capacitor (on the order of 50 pF to 500 pF) across the circuit input.

Most power amplifiers do not drive highly capacitive loads well, and the LM675 is no exception. If the output of the LM675 is connected directly to a capacitor with no series resistance, the square wave response will exhibit ringing if the capacitance is greater than about 0.1 μF . The amplifier can typically drive load capacitances up to 2 μF or so without oscillating, but this is not recommended. If highly capacitive loads are expected, a resistor (at least 1 Ω) should be placed in series with the output of the LM675. A method commonly employed to protect amplifiers from low impedances at high frequencies is to couple to the load through a 10 Ω resistor in parallel with a 5 μH inductor.

CURRENT LIMIT AND SAFE OPERATING AREA (SOA) PROTECTION

A power amplifier's output transistors can be damaged by excessive applied voltage, current flow, or power dissipation. The voltage applied to the amplifier is limited by the design of the external power supply, while the maximum current passed by the output devices is usually limited by internal circuitry to some fixed value. Short-term power dissipation is usually not limited in monolithic operational power amplifiers, and this can be a problem when driving reactive loads, which may draw large currents while high voltages appear on the output transistors. The LM675 not only limits current to around 4A, but also reduces the value of the limit current when an output transistor has a high voltage across it.

When driving nonlinear reactive loads such as motors or loudspeakers with built-in protection relays, there is a possibility that an amplifier output will be connected to a load whose terminal voltage may attempt to swing beyond the power supply voltages applied to the amplifier. This can cause degradation of the output transistors or catastrophic failure of the whole circuit. The standard protection for this

type of failure mechanism is a pair of diodes connected between the output of the amplifier and the supply rails. These are part of the internal circuitry of the LM675, and needn't be added externally when standard reactive loads are driven.

THERMAL PROTECTION

The LM675 has a sophisticated thermal protection scheme to prevent long-term thermal stress to the device. When the temperature on the die reaches 170°C, the LM675 shuts down. It starts operating again when the die temperature drops to about 145°C, but if the temperature again begins to rise, shutdown will occur at only 150°C. Therefore, the device is allowed to heat up to a relatively high temperature if the fault condition is temporary, but a sustained fault will limit the maximum die temperature to a lower value. This greatly reduces the stresses imposed on the IC by thermal cycling, which in turn improves its reliability under sustained fault conditions. This circuitry is 100% tested without a heat sink.

Since the die temperature is directly dependent upon the heat sink, the heat sink should be chosen for thermal resistance low enough that thermal shutdown will not be reached during normal operation. Using the best heat sink possible within the cost and space constraints of the system will improve the long-term reliability of any power semiconductor.

POWER DISSIPATION AND HEAT SINKING

The LM675 should always be operated with a heat sink, even though at idle worst case power dissipation will be only 1.8W (30 mA \times 60V) which corresponds to a rise in die temperature of 97°C above ambient assuming $\theta_{JA} = 54^\circ\text{C/W}$ for a TO-220 package. This in itself will not cause the thermal protection circuitry to shut down the amplifier when operating at room temperature, but a mere 0.9W of additional power dissipation will shut the amplifier down since T_J will then increase from 122°C (97°C + 25°C) to 170°C.

In order to determine the appropriate heat sink for a given application, the power dissipation of the LM675 in that application must be known. When the load is resistive, the maximum average power that the IC will be required to dissipate is approximately:

$$P_D(\text{MAX}) \approx \frac{V_S^2}{2\pi^2 R_L} + P_Q$$

where V_S is the total power supply voltage across the LM675, R_L is the load resistance and P_Q is the quiescent power dissipation of the amplifier. The above equation is only an approximation which assumes an "ideal" class B output stage and constant power dissipation in all other parts of the circuit. As an example, if the LM675 is operated on a 50V power supply with a resistive load of 8 Ω , it can develop up to 19W of internal power dissipation. If the die temperature is to remain below 150°C for ambient temperatures up to 70°C, the total junction-to-ambient thermal resistance must be less than

$$\frac{150^\circ\text{C} - 70^\circ\text{C}}{19\text{W}} = 4.2^\circ\text{C/W}.$$

Using $\theta_{JC} = 2^\circ\text{C/W}$, the sum of the case-to-heat sink interface thermal resistance and the heat-sink-to-ambient

Application Hints (Continued)

thermal resistance must be less than $2.2^{\circ}\text{C}/\text{W}$. The case-to-heat-sink thermal resistance of the TO-220 package varies with the mounting method used. A metal-to-metal interface will be about $1^{\circ}\text{C}/\text{W}$ if lubricated, and about $1.2^{\circ}\text{C}/\text{W}$ if dry. If a mica insulator is used, the thermal resistance will be about $1.6^{\circ}\text{C}/\text{W}$ lubricated and $3.4^{\circ}\text{C}/\text{W}$ dry. For this example, we assume a lubricated mica insulator between the LM675 and the heat sink. The heat sink thermal resistance must then be less than

$$4.2^{\circ}\text{C}/\text{W} - 2^{\circ}\text{C}/\text{W} - 1.6^{\circ}\text{C}/\text{W} = 0.6^{\circ}\text{C}/\text{W}.$$

This is a rather large heat sink and may not be practical in some applications. If a smaller heat sink is required for reasons of size or cost, there are two alternatives. The maximum ambient operating temperature can be restricted to 50°C (122°F), resulting in a $1.6^{\circ}\text{C}/\text{W}$ heat sink, or the heat

sink can be isolated from the chassis so the mica washer is not needed. This will change the required heat sink to a $1.2^{\circ}\text{C}/\text{W}$ unit if the case-to-heat-sink interface is lubricated.

The thermal requirements can become more difficult when an amplifier is driving a reactive load. For a given magnitude of load impedance, a higher degree of reactance will cause a higher level of power dissipation within the amplifier. As a general rule, the power dissipation of an amplifier driving a 60° reactive load will be roughly that of the same amplifier driving the resistive part of that load. For example, some reactive loads may at some frequency have an impedance with a magnitude of 8Ω and a phase angle of 60° . The real part of this load will then be $8\Omega \times \cos 60^{\circ}$ or 4Ω , and the amplifier power dissipation will roughly follow the curve of power dissipation with a 4Ω load.

Typical Applications (Continued)

Non-Inverting Unity Gain Operation

$$R_1 C \geq \frac{1}{2\pi 500 \text{ kHz}}$$

$$R_1 \leq \frac{R_S + R_2}{10}$$

$$A_{V(DC)} = 1$$

TL/H/6739-9

LM741/LM741A/LM741C/LM741E Operational Amplifier

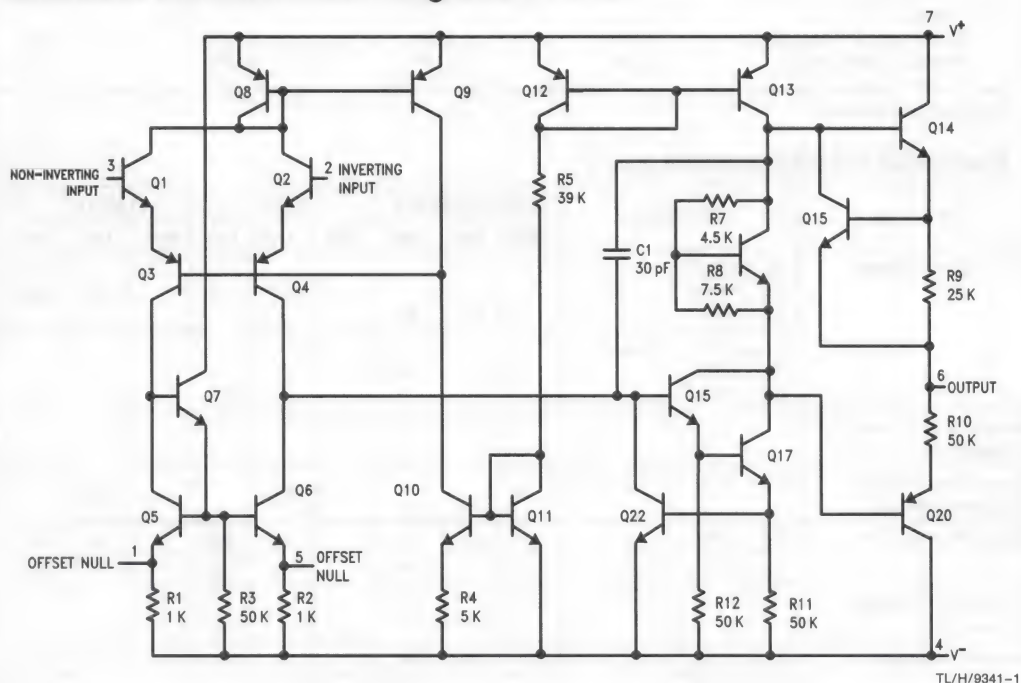

General Description

The LM741 series are general purpose operational amplifiers which feature improved performance over industry standards like the LM709. They are direct, plug-in replacements for the 709C, LM201, MC1439 and 748 in most applications. The amplifiers offer many features which make their application nearly foolproof: overload protection on the input and

output, no latch-up when the common mode range is exceeded, as well as freedom from oscillations.

The LM741C/LM741E are identical to the LM741/LM741A except that the LM741C/LM741E have their performance guaranteed over a 0°C to +70°C temperature range, instead of -55°C to +125°C.

Note 2: For supply voltages less than $\pm 15V$, the absolute maximum input voltage is equal to the supply voltage.

Note 3: Unless otherwise specified, these specifications apply for $V_S = \pm 15V$, $-55^\circ\text{C} \leq T_A \leq +125^\circ\text{C}$ (LM741/LM741A). For the LM741C/LM741E, these specifications are limited to $0^\circ\text{C} \leq T_A \leq +70^\circ\text{C}$.

Note 4: Calculated value from: $BW\text{ (MHz)} = 0.35/\text{Rise Time}(\mu\text{s})$.

Note 5: For military specifications see RETS741X for LM741 and RETS741AX for LM741A.

PRELIMINARY

LM833 Dual Audio Operational Amplifier

General Description

The LM833 is a dual general purpose operational amplifier designed with particular emphasis on performance in audio systems.

This dual amplifier IC utilizes new circuit and processing techniques to deliver low noise, high speed and wide bandwidth without increasing external components or decreasing stability. The LM833 is internally compensated for all closed loop gains and is therefore optimized for all preamp and high level stages in PCM and HiFi systems.

The LM833 is pin-for-pin compatible with industry standard dual operational amplifiers.

Features

- Wide dynamic range > 140 dB
- Low input noise voltage 4.5 nV/ $\sqrt{\text{Hz}}$
- High slew rate 7 V/ μs (typ)
5 V/ μs (min)
- High gain bandwidth product 15 MHz (typ)
10 MHz (min)
- Wide power bandwidth 120 kHz
- Low distortion 0.002%
- Low offset voltage 0.3 mV
- Large phase margin 60°

Application Hints

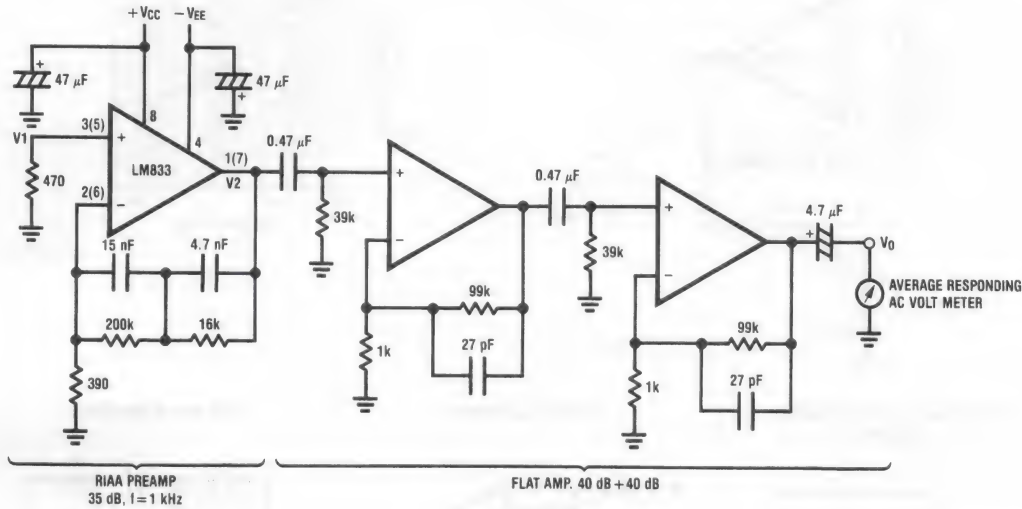

The LM833 is a high speed op amp with excellent phase margin and stability. Capacitive loads up to 50 pF will cause little change in the phase characteristics of the amplifiers and are therefore allowable.

Capacitive loads greater than 50 pF must be isolated from the output. The most straightforward way to do this is to put a resistor in series with the output. This resistor will also prevent excess power dissipation if the output is accidentally shorted.

Noise Measurement Circuit

LM833

Complete shielding is required to prevent induced pick up from external sources. Always check with oscilloscope for power line noise.

LM837 Low Noise Quad Operational Amplifier

General Description

The LM837 is a quad operational amplifier designed for low noise, high speed and wide bandwidth performance. It has a new type of output stage which can drive a 600Ω load, making it ideal for almost all digital audio, graphic equalizer, pre-amplifiers, and professional audio applications. Its high performance characteristics also make it suitable for instrumentation applications where low noise is the key consideration.

The LM837 is internally compensated for unity gain operation. It is pin compatible with most other standard quad op amps and can therefore be used to upgrade existing systems with little or no change.

Features

■ High slew rate	10 V/ μ s (typ) 8 V/ μ s (min)
■ Wide gain bandwidth product	25 MHz (typ) 15 MHz (min)
■ Power bandwidth	200 kHz (typ)
■ High output current	± 40 mA
■ Excellent output drive performance	$> 600\Omega$
■ Low input noise voltage	4.5 nV/ $\sqrt{\text{Hz}}$
■ Low total harmonic distortion	0.0015%
■ Low offset voltage	0.3 mV

LM1558/LM1458 Dual Operational Amplifier

General Description

The LM1558 and the LM1458 are general purpose dual operational amplifiers. The two amplifiers share a common bias network and power supply leads. Otherwise, their operation is completely independent.

The LM1458 is identical to the LM1558 except that the LM1458 has its specifications guaranteed over the temperature range from 0°C to +70°C instead of -55°C to +125°C.

Features

- No frequency compensation required
- Short-circuit protection
- Wide common-mode and differential voltage ranges
- Low-power consumption
- 8-lead TO-5 and 8-lead mini DIP
- No latch up when input common mode range is exceeded

Electrical Characteristics (Note 3)

Parameter	Conditions	LM1558			LM1458			Units
		Min	Typ	Max	Min	Typ	Max	
Input Offset Voltage	$T_A = 25^\circ\text{C}$, $R_S \leq 10\text{ k}\Omega$		1.0	5.0		1.0	6.0	mV
Input Offset Current	$T_A = 25^\circ\text{C}$		80	200		80	200	nA
Input Bias Current	$T_A = 25^\circ\text{C}$		200	500		200	500	nA
Input Resistance	$T_A = 25^\circ\text{C}$	0.3	1.0		0.3	1.0		M Ω
Supply Current Both Amplifiers	$T_A = 25^\circ\text{C}$, $V_S = \pm 15\text{V}$		3.0	5.0		3.0	5.6	mA
Large Signal Voltage Gain	$T_A = 25^\circ\text{C}$, $V_S = \pm 15\text{V}$ $V_{OUT} = \pm 10\text{V}$, $R_L \geq 2\text{ k}\Omega$	50	160		20	160		V/mV
Input Offset Voltage	$R_S \leq 10\text{ k}\Omega$			6.0			7.5	mV
Input Offset Current				500			300	nA
Input Bias Current				1.5			0.8	μA
Large Signal Voltage Gain	$V_S = \pm 15\text{V}$, $V_{OUT} = \pm 10\text{V}$ $R_L \geq \text{k}\Omega$	25			15			V/mV
Output Voltage Swing	$V_S = \pm 15\text{V}$, $R_L = 10\text{ k}\Omega$ $R_L = 2\text{ k}\Omega$	± 12	± 14		± 12	± 14		V
		± 10	± 13		± 10	± 13		V
Input Voltage Range	$V_S = \pm 15\text{V}$	± 12			± 12			V
Common Mode Rejection Ratio	$R_S \leq 10\text{ k}\Omega$	70	90		70	90		dB
Supply Voltage Rejection Ratio	$R_S \leq 10\text{ k}\Omega$	77	96		77	96		dB

Note 1: The maximum junction temperature of the LM1558 is 150°C, while that of the LM1458 is 100°C. For operating at elevated temperatures, devices in the TO-5 package must be derated based on a thermal resistance of 150°C/W, junction to ambient or 45°C/W, junction to case. For the DIP the device must be derated based on a thermal resistance of 187°C/W, junction to ambient.

Note 2: For supply voltages less than ±15V, the absolute maximum input voltage is equal to the supply voltage.

Note 3: These specifications apply for $V_S = \pm 15\text{V}$ and $-55^\circ\text{C} \leq T_A \leq 125^\circ\text{C}$, unless otherwise specified. With the LM1458, however, all specifications are limited to $0^\circ\text{C} \leq T_A \leq 70^\circ\text{C}$ and $V_S = \pm 15\text{V}$.

Note 4: Refer to RETS 1558V for LM1558J and LM1558H military specifications.

National
Semiconductor
Corporation

LM2900/LM3900, LM3301, LM3401 Quad Amplifiers

General Description

The LM2900 series consists of four independent, dual input, internally compensated amplifiers which were designed specifically to operate off of a single power supply voltage and to provide a large output voltage swing. These amplifiers make use of a current mirror to achieve the non-inverting input function. Application areas include: ac amplifiers, RC active filters, low frequency triangle, squarewave and pulse waveform generation circuits, tachometers and low speed, high voltage digital logic gates.

Features

- Wide single supply voltage $4 V_{DC}$ to $32 V_{DC}$
Range or dual supplies $\pm 2 V_{DC}$ to $\pm 16 V_{DC}$
- Supply current drain independent of supply voltage
- Low input biasing current 30 nA
- High open-loop gain 70 dB
- Wide bandwidth 2.5 MHz (unity gain)
- Large output voltage swing $(V^+ - 1) V_{p-p}$
- Internally frequency compensated for unity gain
- Output short-circuit protection

Note 1: For operating at high temperatures, the device must be derated based on a 125°C maximum junction temperature and a thermal resistance of 92°C/W which applies for the device soldered in a printed circuit board, operating in a still air ambient.

Note 2: The output current sink capability can be increased for large signal conditions by overdriving the inverting input. This is shown in the section on Typical Characteristics.

Note 3: This spec indicates the current gain of the current mirror which is used as the non-inverting input.

Note 4: Input V_{BE} match between the non-inverting and the inverting inputs occurs for a mirror current (non-inverting input current) of approximately $10\text{ }\mu\text{A}$. This is therefore a typical design center for many of the application circuits.

Note 5: Clamp transistors are included on the IC to prevent the input voltages from swinging below ground more than approximately $-0.3\text{ V}_{\text{DC}}$. The negative input currents which may result from large signal overdrive with capacitance input coupling need to be externally limited to values of approximately 1 mA . Negative input currents in excess of 4 mA will cause the output voltage to drop to a low voltage. This maximum current applies to any one of the input terminals. If more than one of the input terminals are simultaneously driven negative smaller maximum currents are allowed. Common-mode current biasing can be used to prevent negative input voltages; see for example, the "Differentiator Circuit" in the applications section.

Note 6: These specs apply for $-40^\circ\text{C} \leq T_A \leq +85^\circ\text{C}$, unless otherwise stated.

Application Hints

When driving either input from a low-impedance source, a limiting resistor should be placed in series with the input lead to limit the peak input current. Currents as large as 20 mA will not damage the device, but the current mirror on the non-inverting input will saturate and cause a loss of mirror gain at mA current levels—especially at high operating temperatures.

Precautions should be taken to insure that the power supply for the integrated circuit never becomes reversed in polarity or that the unit is not inadvertently installed backwards in a test socket as an unlimited current surge through the resulting forward diode within the IC could cause fusing of the internal conductors and result in a destroyed unit.

Output short circuits either to ground or to the positive power supply should be of short time duration. Units can be destroyed, not as a result of the short circuit current causing metal fusing, but rather due to the large increase in IC chip dissipation which will cause eventual failure due to excessive junction temperatures. For example, when operating from a well-regulated $+5\text{ V}_{\text{DC}}$ power supply at $T_A = 25^\circ\text{C}$ with a $100\text{ k}\Omega$ shunt-feedback resistor (from the output to the inverting input) a short directly to the power supply will not cause catastrophic failure but the current magnitude will be approximately 50 mA and the junction temperature will be above T_J max. Larger feedback resistors will reduce the current, $11\text{ M}\Omega$ provides approximately 30 mA , an open circuit provides 1.3 mA , and a direct connection from the output to the non-inverting input will result in catastrophic failure when the output is shorted to V^+ as this then places the base-emitter junction of the input transistor directly across the power supply. Short-circuits to ground will have magnitudes of approximately 30 mA and will not cause catastrophic failure at $T_A = 25^\circ\text{C}$.

Unintentional signal coupling from the output to the non-inverting input can cause oscillations. This is likely only in breadboard hook-ups with long component leads and can be prevented by a more careful lead dress or by locating the non-inverting input biasing resistor close to the IC. A quick check of this condition is to bypass the non-inverting input to ground with a capacitor. High impedance biasing resistors used in the non-inverting input circuit make this input lead highly susceptible to unintentional AC signal pickup.

Operation of this amplifier can be best understood by noticing that input currents are differenced at the inverting-input terminal and this difference current then flows through the external feedback resistor to produce the output voltage. Common-mode current biasing is generally useful to allow operating with signal levels near ground or even negative as this maintains the inputs biased at $+V_{\text{BE}}$. Internal clamp transistors (see note 5) catch-negative input voltages at approximately $-0.3\text{ V}_{\text{DC}}$ but the magnitude of current flow has to be limited by the external input network. For operation at high temperature, this limit should be approximately $100\text{ }\mu\text{A}$.

This new "Norton" current-differencing amplifier can be used in most of the applications of a standard IC op amp. Performance as a DC amplifier using only a single supply is not as precise as a standard IC op amp operating with split supplies but is adequate in many less critical applications. New functions are made possible with this amplifier which are useful in single power supply systems. For example, biasing can be designed separately from the AC gain as was shown in the "inverting amplifier," the "difference integrator" allows controlling the charging and the discharging of the integrating capacitor with positive voltages, and the "frequency doubling tachometer" provides a simple circuit which reduces the ripple voltage on a tachometer output DC voltage.

Typical Performance Characteristics

Typical Applications ($V^+ = 15\text{ V}_{\text{DC}}$)

Inverting Amplifier

Triangle/Square Generator

Frequency-Doubling Tachometer

Low $V_{\text{IN}} - V_{\text{OUT}}$ Voltage Regulator

Non-Inverting Amplifier

LM3080/LM3080A

Operational Transconductance Amplifier

General Description

The LM3080 is a programmable transconductance block intended to fulfill a wide variety of variable gain applications. The LM3080 has differential inputs and high impedance push-pull outputs. The device has high input impedance and its transconductance (g_m) is directly proportional to the amplifier bias current (I_{ABC}).

High slew rate together with programmable gain make the LM3080 an ideal choice for variable gain applications such as sample and hold, multiplexing, filtering, and multiplying.

The LM3080N and LM3080AN are guaranteed from 0°C to +70°C.

Features

- Slew rate (unity gain compensated): 50 V/ μ s
- Fully adjustable gain: 0 to $g_m \cdot R_L$ limit
- Extended g_m linearity: 3 decades
- Flexible supply voltage range: $\pm 2V$ to $\pm 18V$
- Adjustable power consumption

LM4250/LM4250C Programmable Operational Amplifier

General Description

The LM4250 and LM4250C are extremely versatile programmable monolithic operational amplifiers. A single external master bias current setting resistor programs the input bias current, input offset current, quiescent power consumption, slew rate, input noise, and the gain-bandwidth product. The device is a truly general purpose operational amplifier.

The LM4250C is identical to the LM4250 except that the LM4250C has its performance guaranteed over a 0°C to +70°C temperature range instead of the -55°C to +125°C temperature range of the LM4250.

Features

- $\pm 1\text{V}$ to $\pm 18\text{V}$ power supply operation
- 3 nA input offset current
- Standby power consumption as low as 500 nW
- No frequency compensation required
- Programmable electrical characteristics
- Offset voltage nulling capability
- Can be powered by two flashlight batteries
- Short circuit protection

Typical Applications

X5 Difference Amplifier

Quiescent $P_D = 0.6\text{ mW}$

TL/H/9300-3

500 Nano-Watt X10 Amplifier

Quiescent $P_P = 500\text{ mW}$

PRELIMINARY

LM6161/LM6261/LM6361 High Speed Operational Amplifier

General Description

The LM6161 family of high-speed amplifiers exhibits an excellent speed-power product in delivering 300 V/ μ s and 50 MHz unity gain stability with only 5 mA of supply current. Further power savings and application convenience are possible by taking advantage of the wide dynamic range in operating supply voltage which extends all the way down to +5V.

These amplifiers are built with National's new VIP™ (Vertically Integrated PNP) process which provides fast PNP transistors that are true complements to the already fast NPN devices. This advanced junction-isolated process delivers high speed performance without the need for complex and expensive dielectric isolation.

Features

- High slew rate 300 V/ μ s
- High unity gain freq 50 MHz
- Low supply current 5 mA
- Fast settling 120 ns to 0.1%
- Low differential gain <0.1%
- Low differential phase 0.1°
- Wide supply range 4.75V to 32V
- Stable with unlimited capacitive load
- Well behaved; easy to apply

Typical AC Characteristics

Step Response; $A_v = +1$ 

TL/H/9057-1

Gain & Phase; $A_v = +100$

Input Noise Current	f = 10 kHz	1.5							pA/√Hz

Note 1: Continuous short-circuit operation at elevated ambient temperature can result in exceeding the maximum allowed junction temperature of 150°C.

Note 2: The typical junction-to-ambient thermal resistance of the molded plastic DIP (N) is 105°C/W, the molded plastic SO (M) package is 155°C/W, the cerdip (J) package is 125°C/W, and the TO-5 (H) package is 155°C/W. All numbers apply for packages soldered directly into a printed circuit board.

Note 3: Unless otherwise specified, all limits guaranteed for T_A = T_J = 25°C with supply voltage = ±15V, V_{CM} = 0V, and R_L ≥ 100 kΩ. **Boldface** limits apply over the range listed under "Operating Temperature Range" with T_A = T_J in the "Absolute Maximum Ratings" section.

Note 4: Guaranteed and 100% production tested. These limits are used to calculate outgoing AQL levels.

Note 5: Guaranteed but not 100% production tested. These limits are not used to calculate outgoing AQL levels.

Note 6: For single supply operation, the following conditions apply: V⁺ = 5V, V⁻ = 0V, V_{CM} = 2.5V, V_{OUT} = 2.5V. Pin 1 & Pin 8 (V_{os} Adjust) are each connected to Pin 4 (V⁻) to realize maximum output swing. This connection will degrade V_{OS}, V_{OS} Drift, and Input Voltage Noise.

Note 7: C_L ≤ 5 pF.

Note 8: In order to achieve optimum AC performance, the input stage was designed without protective clamps. Exceeding the maximum differential input voltage results in reverse breakdown of the base-emitter junction of one of the input transistors and probable degradation of the input parameters (especially V_{os}, I_{os}, and Noise).

Note 9: The average voltage that the weakest pin combinations (those involving Pin 2 or Pin 3) can withstand and still conform to the datasheet limits. The test circuit used consists of the human body model of 100 pF in series with 1500Ω.

Note 10: V_{IN} = 8V step. For V⁺ = ±5V, V_{IN} = 5V step.

Note 11: Voltage Gain is the total output swing (20V) divided by the input signal required to produce that swing.

Note 1: Continuous short-circuit operation at elevated ambient temperature can result in exceeding the maximum allowed junction temperature of 150°C.

Note 2: The typical junction-to-ambient thermal resistance of the molded plastic DIP (N) is 105°C/Watt, the molded plastic SO (M) package is 155°C/Watt, the cerdip (J) package is 125°C/Watt, and the TO-5 (H) package is 155°C/Watt. All numbers apply for packages soldered directly into a printed circuit board.

Note 3: Unless otherwise specified, all limits guaranteed for T_a = T_j = 25°C with supply voltage = ±15V, V_{CM} = 0V, and R_L ≥ 100 kΩ. **Boldface** limits apply over the range listed under "Operating Temperature Range".

Note 4: Guaranteed and 100% production tested. These limits are used to calculate outgoing AQL levels.

Note 5: Guaranteed but not 100% production tested. These limits are not used to calculate outgoing AQL levels.

Note 6: For single supply operation, the following conditions apply: V+ = 5V, V- = 0V, V_{CM} = 2.5V, V_{OUT} = 2.5V. Pin 1 & Pin 8 (V_{OS} Adjust) are each connected to Pin 4 (V-) to realize maximum output swing. This connection will degrade V_{OS}.

Note 7: C_L ≤ 5 pF.

Note 8: In order to achieve optimum AC performance, the input stage was designed without protective clamps. Exceeding the maximum differential input voltage results in reverse breakdown of the base-emitter junction of one of the input transistors and probable degradation of the input parameters (especially V_{OS}, I_{OS}, and Noise).

Note 9: The average voltage that the weakest pin combinations (those involving Pin 2 or Pin 3) can withstand and still conform to the datasheet limits. The test circuit used consists of the human body model of 100 pF in series with 1500Ω.

Note 10: V_{IN} = 0.7V step. For V+ = ±5V, V_{IN} = 0.2V step.

Note 11: Voltage Gain is the total output swing (20V) divided by the input signal required to produce that swing.

LM13080 Programmable Power Op Amp

General Description

The LM13080 is an internally compensated medium power operational amplifier designed for use in those applications requiring load currents of several hundred milliamperes. This amplifier has the added advantage of having an input stage programmed with an external resistor. The user is able to optimize the amplifier performance for each individual application with this feature. Applications include servo amplifiers and drivers, high input impedance audio amplifiers, DC-to-DC converters, precision power comparators which can either sink or source current and motor speed controls.

The LM13080 may be powered from either single or dual power supplies, and will operate from as little as 3V.

As a power operational amplifier, the LM13080 is capable of delivering 0.25A to a load. This feature allows the system designer to fulfill his medium power circuit requirements without having to add external current boost transistors to the output of a standard operational amplifier.

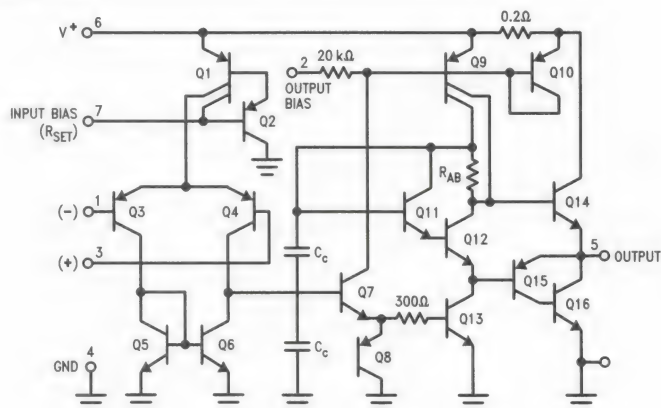

By selecting the proper input stage bias resistor it is possible to tailor the performance of the input stage to meet the needs of any particular system. Trade-offs between input offset voltage, input bias current and gain bandwidth are easily made.

An unusual feature of the LM13080 is an electronic shut-down capability.

Features

- High output current—250 mA
- Externally programmable input stage
- Low power supply operation—3V
- Electronic shut-down capability
- Internally compensated for unity gain
- Low input bias current

Output Voltage Swing V_{OH}	$V_S = \pm 6V$ (Note 1) $R_L = 50\Omega$			4	V
V_{OL}	$R_L = 8\Omega$ $R_L = 50\Omega$ $R_L = 8\Omega$	-4 -1.6		1.6	V V V

Electrical Characteristics $V_S = 12V$, $R_{SET} = 680k$, $0^\circ C \leq T_A \leq 70^\circ C$, unless otherwise specified (Continued)

Parameter	Conditions	Min	Typ	Max	Units
Large Signal Voltage Gain	$V_S = \pm 6V$, $R_L = 50\Omega$, $f = 100\text{ Hz}$	1			V/mV
Input Common-Mode Voltage Range	$V_S \leq 15V$ (Note 3)	1.25		$V_S - 1.75$	V
Common-Mode Rejection Ratio	$T_A = 25^\circ C$	63	85		dB
Total Harmonic Distortion	$R_L = 8\Omega$, $V_O = 2\text{ Vrms}$, $f = 1\text{ kHz}$, $T_A = 25^\circ C$		0.5	5	%

Note 1: For operation at high temperatures, the LM13080 must be derated based upon a maximum junction temperature of $150^\circ C$ and a thermal resistance of $100^\circ C/W$. The thermal resistance values given are for a still air ambient with the package soldered into a printed circuit board.

Note 2: Differential input voltages up to the magnitude of the power supply voltage will not damage the input circuitry. However, input voltages outside the input common-mode voltage range will not be able to properly control the output of the amplifier.

Note 3: The input voltage applied to either input should not be allowed to go more than $0.3V$ below the potential applied to pin 4; however, either input can be taken as high as $15V$ without causing damage to the circuit. Input voltages below the minimum common-mode voltage range may cause a phase reversal in the output.

Note 4: This input current will exist only when the voltage at either input lead is driven negative. It is due to the base-isolation junction of the PNP transistor tub becoming forward biased and thereby acting as an input diode clamp. In addition to this diode action, there is also lateral NPN parasitic action on the IC chip. This transistor action can cause the output to take an undefined state for the time duration that an input is driven negative.

Note 5: $V_O = 6V$, $R_S = 0\Omega$, and over the full input common-mode voltage range.

Note 6: Supply current is measured with the amplifier connected in a unity gain follower configuration and the positive input set to one-half of the supply voltage.

Application Hints

The LM13080 is a power op amp capable of sourcing or sinking more than 250 mA and does not include internal current limit or thermal shut-down. Therefore, the user must make sure that his application will not cause the power dissipation rating of the package to be exceeded. The LM13080 is rated at a maximum dissipation of 1250 mW at 25°C. For operation at temperatures above 25°C, the maximum dissipation must be derated using the equation:

$$P_D = \frac{T_J - T_A}{\Theta_{JA}}$$

where P_D is the maximum allowable power dissipation, T_J is the maximum junction temperature (150°C), T_A is the ambient temperature and Θ_{JA} is the thermal resistance of the package operated in a still air environment. Θ_{JA} for the LM13080N is 100°C/W. For example, if the LM13080N is used in free air in a 70°C ambient, the maximum power that can be dissipated is:

$$P_D = \frac{150^\circ\text{C} - 70^\circ\text{C}}{100^\circ\text{C/W}} = 800 \text{ mW}$$

The LM13080 derives its ability to sink current through the use of a composite NPN/PNP output configuration. This local loop must be compensated by the series connection of a 0.05 μF capacitor and a 10 Ω resistor between the output of the op amp (pin 5) and the negative power supply (pin 4). The RC does not just filter out the oscillation from the output waveform but actually stabilizes the loop.

If the inputs of the LM13080 are driven below the input common-mode voltage range, it is possible that the output will experience a phase reversal. This is particularly true for the non-inverting input ($V_{IN(+)}$). If either input is driven to a voltage level 0.3V below the substrate (pin 4) a parasitic NPN transistor will be turned ON. The emitter of this parasitic transistor is the normal input transistor epi (N-type, base) region, the base is the substrate (P-type) and the collector is every other epi region on the die. Circuit operation in this mode is unpredictable. If an input is forced below the substrate, the current flowing out of that input should be limited to 20 mA to insure that the amplifier will not be destroyed.

Programming the LM13080 is accomplished by selecting the value of R_{SET} , the input stage bias resistor, to optimize the amplifier for each particular application. An example would be an application with low source resistance which requires a low offset voltage to make a precise DC measurement. By selecting an R_{SET} of 100 k Ω , the normal offset voltage would be reduced to approximately one-fourth the value it would be if a 680k resistor was used. By studying the curves, it can be seen that the bias current will increase but an increase here has very little effect due to the small source impedance. It should also be noted that with a 100k input set resistor the gain bandwidth product will also increase, and in fact, the amplifier must be operated with a closed loop voltage gain of 6 to assure stability.

The effect of R_{SET} on the total quiescent supply current will be very small ($\Delta I_S < 5\% I_S$) as long as R_{SET} is 100k or greater.

To employ electronic shut-down the output bias pin, pin 2, and the negative end of the input bias resistor, R_{SET} , are connected to the negative power supply (or ground in a single power system) through a saturated NPN transistor (or other electronic switch). When the transistor is turned OFF, all of the bias currents inside the op amp are turned OFF and all input and output terminals will float. When first turned ON, the output will take about 5 μs to reach the correct level. To insure that the LM13080 is OFF, leakage in the control device must be below the level that will allow pins 2 and 7 to fall to 0.4V below V^+ .

Power supply rejection is a function of the change in voltage across the input bias resistor, R_{SET} . To improve the PSRR of the LM13080, the user must be careful to bypass pin 7 to pin 6 or to establish a floating voltage referenced to the positive power supply to serve as a connection point for R_{SET} . In applications where PSRR is important, it is imperative that a supply bypass capacitor(s) be used.

Typical Applications

LINE DRIVER

The line driver circuit in *Figure 1* is able to accept an unbalanced, high impedance input and convert it to a balanced output suitable for driving a low impedance line. This is particularly useful in an environment where magnetically induced hum or noise pickup is a problem.

The outputs of the 2 LM13080s are of opposite polarity; therefore, terminating the line with a balanced load (i.e., a differential amplifier or a transformer) will cause common-mode interference pickup to be cancelled.

This circuit will drive a 20 Vp-p signal into a 50 Ω load for frequencies up to 10 kHz. Above 10 kHz the output signal is slew rate limited, but the line driver will still supply a 13 Vp-p signal at 20 kHz. The voltage gain of the network is 2, and the low frequency roll-off is determined by:

$$f_L = \frac{1}{2\pi RC}$$

It can be seen that if the load is connected directly between the outputs of the amplifiers, the line driver becomes a simple bridge amplifier capable of delivering 2W into a 16 Ω load.

PIEZOELECTRIC ALARM

The piezoelectric alarm shown in *Figure 2* uses a 3-terminal transducer (Gulton 101FB or equivalent) to produce an 80 dB SPL alarm.

The transducer has a feedback terminal which is connected to the non-inverting input of the LM13080, causing oscillation at the resonant frequency of the piezoelectric crystal. The alarm can be controlled through the use of the electronic shut-down feature of the amplifier. The 100k resistor and 0.1 μF capacitor are used to provide a reference voltage at the inverting input and to keep the duty cycle of the crystal oscillation close to 50%. The RC time constant of this feedback network should be much greater than the time constant of the transducer.

Typical Applications (Continued)

FIGURE 1. Line Driver—Unbalanced Input to Balanced Output

TL/H/7978-5

FIGURE 2. Piezoelectric Alarm

TL/H/7978-6

SIRENS

Two separate circuits for sirens are shown. The first, *Figure 3*, is a 2-state or ON-OFF type siren where the LM13080 oscillates at an audio frequency and drives an 8Ω speaker and the LM339 acts as a switch which controls the audio burst rate. The second siren, *Figure 4*, provides a constant audio output but alternates between 2 separate tones. The LM13080 is set to oscillate at one basic frequency and this frequency is changed by adding a 200 kΩ charging resistor in parallel with the feedback resistor, R2.

LAMP FLASHER—RELAY DRIVER

The LM13080 is easily adaptable to such applications as low frequency warning devices. The output of the oscillator is a squarewave that is used to drive lamps or small relays. As shown in *Figure 5*, the circuit alternately flashes 2 incandescent lamps.

MOTOR SPEED CONTROL

The LM13080 can be used to construct a very simple speed control for small motors requiring less than 0.5A start current. This circuit operates by impressing the multiple of a reference voltage across the motor, and then varying the reference by means of a quasi-positive feedback to change the voltage across the motor any time the load on the motor changes.

To understand the circuit operation, it is easiest to let the voltage at the cathode of diode D1, Figure 6, be the input

voltage, V_{IN} , to the system. Diode D1 is actually a level shift diode to bring V_{IN} into the common-mode range of the amplifier. A reference voltage is established by the combined voltage drop through the 10Ω potentiometer, R3 and the reference diode, D2 and is applied to the non-inverting input of the LM13080. Resistor R4 is a bias resistor used to keep D2 active. The 10k speed adjust potentiometer is 2 resistors in 1, where section R1 is the input resistance and section R2 is the negative feedback resistance. It can be seen that the voltage impressed across the motor is equal to:

$$V_{MOTOR} = \frac{(V_{BE2} + I_3 R_3) R_2}{R_1} + V_{BE}$$

Typical Applications (Continued)

The positive feedback is developed as a change in the voltage across R3 due to the change in the motor current caused by a variation in the motor's load. Resistor R3 is shown as a potentiometer so that the amount of positive feedback can be adjusted for smooth operation of the motor. Capacitor C1 and resistor R5 serve as a filter for the reference voltage at the non-inverting input of the amplifier.

VOLTAGE REGULATORS

In normal, positive or negative regulator application such as those shown in Figure 7 and Figure 8, the LM13080 has 2 major advantages over standard operational amplifiers. The LM13080 has its own on-chip pass device and in addition can either sink or source 250 mA of load current.

LM13600/LM13600A

Dual Operational Transconductance Amplifiers with Linearizing Diodes and Buffers

General Description

The LM13600 series consists of two current controlled transconductance amplifiers each with differential inputs and a push-pull output. The two amplifiers share common supplies but otherwise operate independently. Linearizing diodes are provided at the inputs to reduce distortion and allow higher input levels. The result is a 10 dB signal-to-noise improvement referenced to 0.5 percent THD. Controlled impedance buffers are provided which are especially designed to complement the dynamic range of the amplifiers.

Features

- g_m adjustable over 6 decades
- Excellent g_m linearity

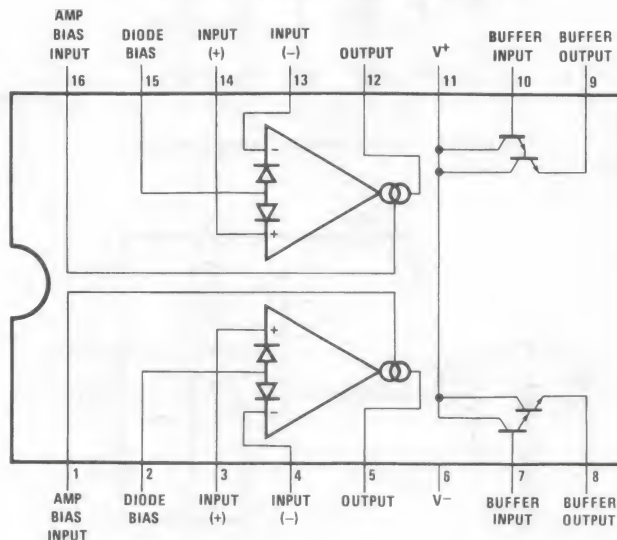

- Excellent matching between amplifiers
- Linearizing diodes
- Controlled impedance buffers
- High output signal-to-noise ratio
- Wide supply range $\pm 2V$ to $\pm 22V$

Applications

- Current-controlled amplifiers
- Current-controlled impedances
- Current-controlled filters
- Current-controlled oscillators
- Multiplexers
- Timers
- Sample and hold circuits

Circuit Description

The differential transistor pair Q_4 and Q_5 form a transconductance stage in that the ratio of their collector currents is defined by the differential input voltage according to the transfer function:

$$V_{IN} = \frac{kT}{q} \ln \frac{I_5}{I_4} \quad (1)$$

where V_{IN} is the differential input voltage, kT/q is approximately 26 mV at 25°C and I_5 and I_4 are the collector currents of transistors Q_5 and Q_4 respectively. With the exception of Q_3 and Q_{13} , all transistors and diodes are identical in size. Transistors Q_1 and Q_2 with Diode D_1 form a current mirror which forces the sum of currents I_4 and I_5 to equal I_{ABC} :

$$I_4 + I_5 = I_{ABC} \quad (2)$$

where I_{ABC} is the amplifier bias current applied to the gain pin.

For small differential input voltages the ratio of I_4 and I_5 approaches unity and the Taylor series of the \ln function can be approximated as:

$$\frac{kT}{q} \ln \frac{I_5}{I_4} \approx \frac{kT}{q} \frac{I_5 - I_4}{I_4} \quad (3)$$

$$I_4 \approx I_5 \approx \frac{I_{ABC}}{2}$$

$$V_{IN} \left[\frac{I_{ABC} q}{2kT} \right] = I_5 - I_4 \quad (5)$$

Collector currents I_4 and I_5 are not very useful by themselves and it is necessary to subtract one current from the

other. The remaining transistors and diodes form three current mirrors that produce an output current equal to I_5 minus I_4 thus:

$$V_{IN} \left[\frac{I_{ABC} q}{2kT} \right] = I_{OUT} \quad (5)$$

The term in brackets is then the transconductance of the amplifier and is proportional to I_{ABC} .

Linearizing Diodes

For differential voltages greater than a few millivolts, Equation 3 becomes less valid and the transconductance becomes increasingly nonlinear. Figure 1 demonstrates how the internal diodes can linearize the transfer function of the amplifier. For convenience assume the diodes are biased with current sources and the input signal is in the form of current I_S . Since the sum of I_4 and I_5 is I_{ABC} and the difference is I_{OUT} , currents I_4 and I_5 can be written as follows:

$$I_4 = \frac{I_{ABC}}{2} - \frac{I_{OUT}}{2}, \quad I_5 = \frac{I_{ABC}}{2} + \frac{I_{OUT}}{2}$$

Since the diodes and the input transistors have identical geometries and are subject to similar voltages and temperatures, the following is true:

$$\begin{aligned} \frac{kT}{q} \ln \frac{\frac{I_D}{2} + I_S}{\frac{I_D}{2} - I_S} &= \frac{kT}{q} \ln \frac{\frac{I_{ABC}}{2} + \frac{I_{OUT}}{2}}{\frac{I_{ABC}}{2} - \frac{I_{OUT}}{2}} \\ \therefore I_{OUT} &= I_S \left(\frac{2I_{ABC}}{I_D} \right) \quad \text{for } |I_S| < \frac{I_D}{2} \end{aligned} \quad (6)$$

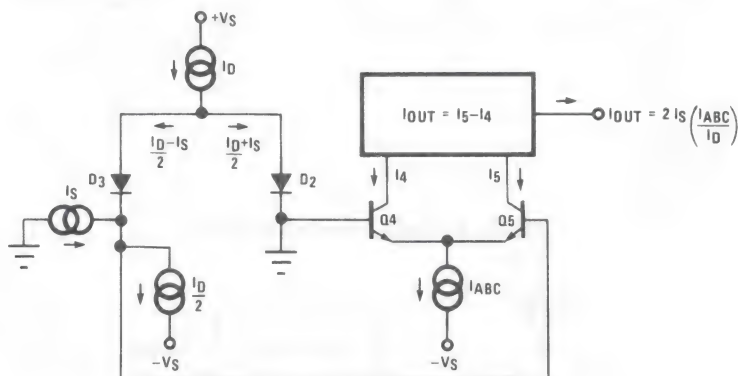

FIGURE 1. Linearizing Diodes

TL/H/7980-8

Linearizing Diodes (Continued)

Notice that in deriving Equation 6 no approximations have been made and there are no temperature-dependent terms. The limitations are that the signal current not exceed $I_D/2$ and that the diodes be biased with currents. In practice, replacing the current sources with resistors will generate insignificant errors.

Controlled Impedance Buffers

The upper limit of transconductance is defined by the maximum value of I_{ABC} (2 mA). The lowest value of I_{ABC} for which the amplifier will function therefore determines the overall dynamic range. At very low values of I_{ABC} , a buffer which has very low input bias current is desirable. An FET follower satisfies the low input current requirement, but is somewhat non-linear for large voltage swing. The controlled impedance buffer is a Darlington which modifies its input bias current to suit the need. For low values of I_{ABC} , the buffer's input current is minimal. At higher levels of I_{ABC} , transistor Q_3 biases up Q_{12} with a current proportional to I_{ABC} for fast slew rate.

Applications—Voltage Controlled Amplifiers

Figure 2 shows how the linearizing diodes can be used in a voltage-controlled amplifier. To understand the input biasing, it is best to consider the 13 k Ω resistor as a current source and use a Thevenin equivalent circuit as shown in Figure 3. This circuit is similar to Figure 1 and operates the same. The potentiometer in Figure 2 is adjusted to minimize the effects of the control signal at the output.

For optimum signal-to-noise performance, I_{ABC} should be as large as possible as shown by the Output Voltage vs. Amplifier Bias Current graph. Larger amplitudes of input signal also improve the S/N ratio. The linearizing diodes help here by allowing larger input signals for the same output distortion as shown by the Distortion vs. Differential Input Voltage graph. S/N may be optimized by adjusting the magnitude of the input signal via R_{IN} (Figure 2) until the output distortion is below some desired level. The output voltage swing can then be set at any level by selecting R_L .

Although the noise contribution of the linearizing diodes is negligible relative to the contribution of the amplifier's internal transistors, I_D should be as large as possible. This minimizes the dynamic junction resistance of the diodes (r_d) and maximizes their linearizing action when balanced against R_{IN} . A value of 1 mA is recommended for I_D unless the specific application demands otherwise.

FIGURE 2. Voltage Controlled Amplifier

TL/H/7980-9

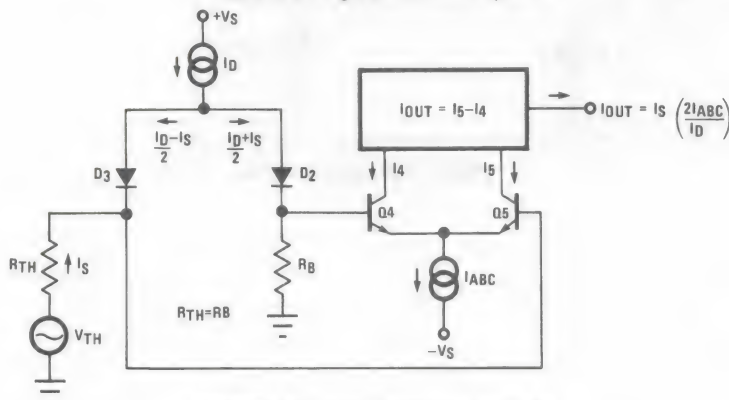

FIGURE 3. Equivalent VCA Input Circuit

TL/H/7980-10

Stereo Volume Control

The circuit of Figure 4 uses the excellent matching of the two LM13600 amplifiers to provide a Stereo Volume Control with a typical channel-to-channel gain tracking of 0.3 dB. R_P is provided to minimize the output offset voltage and may be replaced with two 510 Ω resistors in AC-coupled applications. For the component values given, amplifier gain is derived for Figure 2 as being:

$$\frac{V_O}{V_{IN}} = 940 \times I_{ABC}$$

If V_C is derived from a second signal source then the circuit becomes an amplitude modulator or two-quadrant multiplier as shown in Figure 5, where:

$$I_O = \frac{-2I_S}{I_D} (I_{ABC}) = \frac{-2I_S}{I_D} \frac{V_{IN2}}{R_C} - \frac{2I_S}{I_D} \frac{(V^- + 1.4V)}{R_C}$$

FIGURE 4. Stereo Volume Control

TL/H/7980-11

FIGURE 5. Amplitude Modulator

TL/H/7980-12

Stereo Volume Control (Continued)

The constant term in the above equation may be cancelled by feeding $I_S \times I_D R_C / 2 (V^- + 1.4V)$ into I_D . The circuit of *Figure 6* adds R_M to provide this current, resulting in a four-quadrant multiplier where R_C is trimmed such that $V_O = 0V$ for $V_{IN2} = 0V$. R_M also serves as the load resistor for I_D .

Noting that the gain of the LM13600 amplifier of *Figure 3* may be controlled by varying the linearizing diode current I_D as well as by varying I_{ABC} , *Figure 7* shows an AGC Amplifier using this approach. As V_O reaches a high enough amplitude ($3 V_{BE}$) to turn on the Darlington transistors and the linearizing diodes, the increase in I_D reduces the amplifier gain so as to hold V_O at that level.

Voltage Controlled Resistors

An Operational Transconductance Amplifier (OTA) may be used to implement a Voltage Controlled Resistor as shown

in *Figure 8*. A signal voltage applied at R_X generates a V_{IN} to the LM13600 which is then multiplied by the g_m of the amplifier to produce an output current, thus:

$$R_X = \frac{R + R_A}{g_m R_A}$$

where $g_m \approx 19.2 I_{ABC}$ at $25^\circ C$. Note that the attenuation of V_O by R and R_A is necessary to maintain V_{IN} within the linear range of the LM13600 input.

Figure 9 shows a similar VCR where the linearizing diodes are added, essentially improving the noise performance of the resistor. A floating VCR is shown in *Figure 10*, where each "end" of the "resistor" may be at any voltage within the output voltage range of the LM13600.

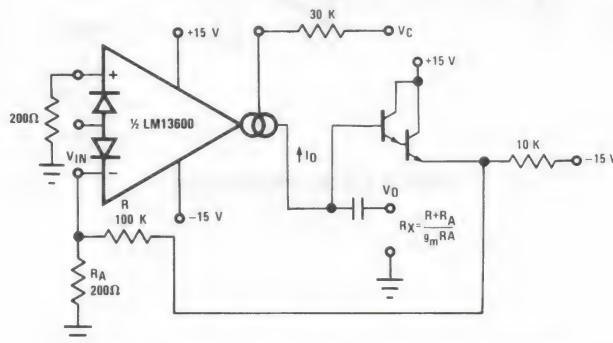

FIGURE 8. Voltage Controlled Resistor, Single-Ended

TL/H/7980-15

Voltage Controlled Filters

OTA's are extremely useful for implementing voltage controlled filters, with the LM13600 having the advantage that the required buffers are included on the I.C. The VC Lo-Pass Filter of Figure 11 performs as a unity-gain buffer amplifier at frequencies below cut-off, with the cut-off frequency being the point at which X_C/g_m equals the closed-loop gain of (R/R_A). At frequencies above cut-off the circuit provides a single RC roll-off (6 dB per octave) of the input signal amplitude with a -3 dB point defined by the given equation,

where g_m is again $19.2 \times I_{ABC}$ at room temperature. Figure 12 shows a VC High-Pass Filter which operates in much the same manner, providing a single RC roll-off below the defined cut-off frequency.

Additional amplifiers may be used to implement higher order filters as demonstrated by the two-pole Butterworth Lo-Pass Filter of Figure 13 and the state variable filter of Figure 14. Due to the excellent g_m tracking of the two amplifiers and the varied bias of the buffer Darlington's, these filters perform well over several decades of frequency.

Voltage Controlled Oscillators

The classic Triangular/Square Wave VCO of *Figure 15* is one of a variety of Voltage Controlled Oscillators which may be built utilizing the LM13600. With the component values shown, this oscillator provides signals from 200 kHz to below 2 Hz as I_C is varied from 1 mA to 10 nA. The output amplitudes are set by $I_A \times R_A$. Note that the peak differential input voltage must be less than 5V to prevent zenering the inputs.

A few modifications to this circuit produce the ramp/pulse VCO of *Figure 16*. When V_{O2} is high, I_F is added to I_C to

increase amplifier A1's bias current and thus to increase the charging rate of capacitor C. When V_{O2} is low, I_F goes to zero and the capacitor discharge current is set by I_C .

The VC Lo-Pass Filter of *Figure 11* may be used to produce a high-quality sinusoidal VCO. The circuit of *Figure 16* employs two LM13600 packages, with three of the amplifiers configured as lo-pass filters and the fourth as a limiter/inverter. The circuit oscillates at the frequency at which the loop phase-shift is 360° or 180° for the inverter and 60° per filter stage. This VCO operates from 5 Hz to 50 kHz with less than 1% THD.

FIGURE 18. Single Amplifier VCO

Figure 18 shows how to build a VCO using one amplifier when the other amplifier is needed for another function.

Additional Applications

Figure 19 presents an interesting one-shot which draws no power supply current until it is triggered. A positive-going trigger pulse of at least 2V amplitude turns on the amplifier through R_B and pulls the non-inverting input high. The amplifier regenerates and latches its output high until capacitor C charges to the voltage level on the non-inverting input. The output then switches low, turning off the amplifier and discharging the capacitor. The capacitor discharge rate is increased by shorting the diode bias pin to the inverting input so that an additional discharge current flows through D_1 when the amplifier output switches low. A special feature of this timer is that the other amplifier, when biased from V_O , can perform another function and draw zero stand-by power as well.

The operation of the multiplexer of Figure 20 is very straightforward. When A1 is turned on it holds V_O equal to V_{IN1} and when A2 is supplied with bias current then it controls V_O . C_C and R_C serve to stabilize the unity-gain configuration of amplifiers A1 and A2. The maximum clock rate is limited to about 200 kHz by the LM13600 slew rate into 150 pF when the $(V_{IN1}-V_{IN2})$ differential is at its maximum allowable value of 5V.

The Phase-Locked Loop of Figure 21 uses the four-quadrant multiplier of Figure 6 and the VCO of Figure 18 to produce a PLL with a $\pm 5\%$ hold-in range and an input sensitivity of about 300 mV.

Additional Applications (Continued)

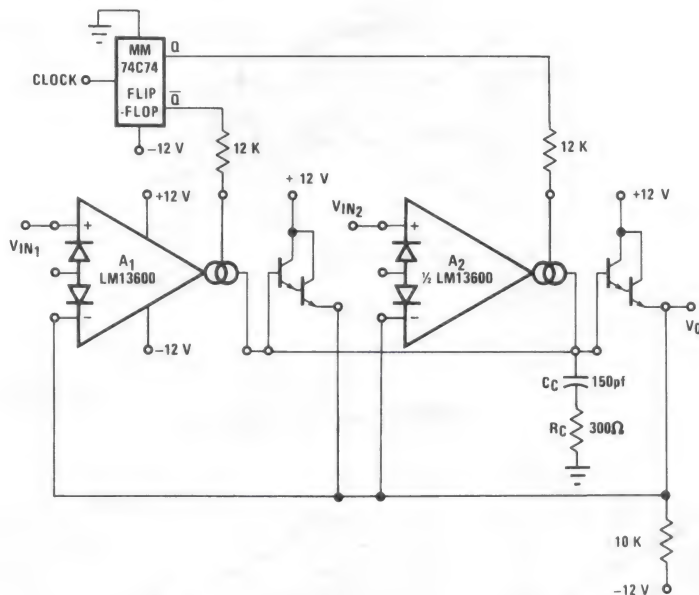

FIGURE 20. Multiplexer

TL/H/7980-27

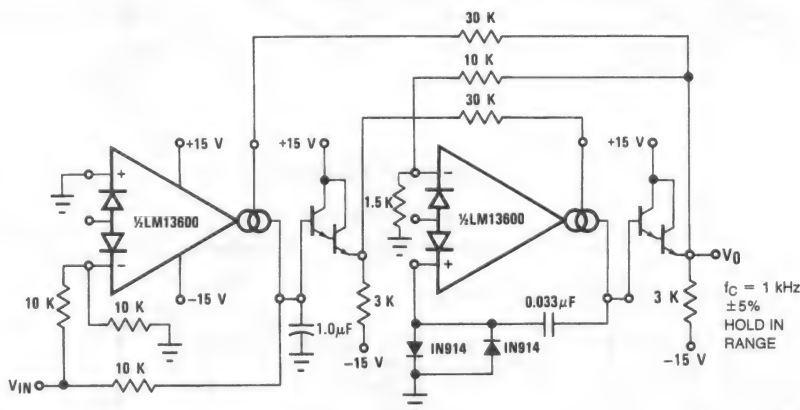

FIGURE 21. Phase Lock Loop

TL/H/7980-28

The Schmitt Trigger of Figure 22 uses the amplifier output current into R to set the hysteresis of the comparator; thus $V_H = 2 \times R \times I_B$. Varying I_B will produce a Schmitt Trigger with variable hysteresis.

Figure 23 shows a Tachometer or Frequency-to-Voltage converter. Whenever A1 is toggled by a positive-going input, an amount of charge equal to $(V_H - V_L) C_f$ is sourced into C_f and R_f . This once-per-cycle charge is then balanced by the current of V_O/R_f . The maximum f_{IN} is limited by the amount of time required to charge C_f from V_L to V_H with a current of I_B , where V_L and V_H represent the maximum low and maxi-

mum high output voltage swing of the LM13600. D1 is added to provide a discharge path for C_f when A1 switches low. The Peak Detector of Figure 24 uses A2 to turn on A1 whenever V_{IN} becomes more positive than V_O . A1 then charges storage capacitor C to hold V_O equal to V_{INPK} . One precaution to observe when using this circuit: the Darlington transistor used must be on the same side of the package as A2 since the A1 Darlington will be turned on and off with A1. Pulling the output of A2 low through D1 serves to turn off A1 so that V_O remains constant.

Additional Applications (Continued)

FIGURE 22. Schmitt Trigger

TL/H/7980-30

FIGURE 23. Tachometer

TL/H/7980-31

FIGURE 24. Peak Detector and Hold Circuit

Additional Applications (Continued)

The Sample-and-Hold circuit of *Figure 25* also requires that the Darlington buffer used be from the other (A2) half of the package and that the corresponding amplifier be biased on continuously. The Ramp-and-Hold of *Figure 26* sources I_B into capacitor C whenever the input to A1 is brought high, giving a ramp-rate of about 1 V/ms for the component values shown.

The true-RMS converter of *Figure 27* is essentially an automatic gain control amplifier which adjusts its gain such that the AC power at the output of amplifier A1 is constant. The output power of amplifier A1 is monitored by squaring amplifier A2 and the average compared to a reference voltage with amplifier A3. The output of A3 provides bias current to the diodes of A1 to attenuate the input signal. Because the output power of A1 is held constant, the RMS value is constant and the attenuation is directly proportional to the RMS value of the input voltage. The attenuation is also proportional to the diode bias current. Amplifier A4 adjusts the ratio of currents through the diodes to be equal and therefore the voltage at the output of A4 is proportional to the RMS value of the input voltage. The calibration potentiometer is set such that V_O reads directly in RMS volts.

FIGURE 25. Sample-Hold Circuit

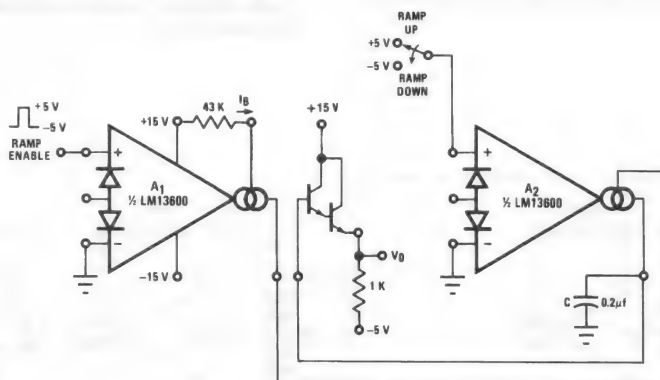

FIGURE 26. Ramp and Hold

TL/H/7980-33

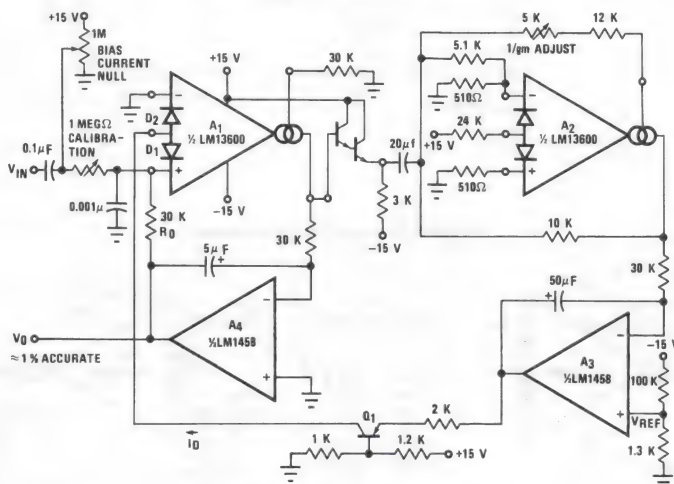

FIGURE 27. True RMS Converter

TL/H/7980-34

Additional Applications (Continued)

The circuit of Figure 28 is a voltage reference of variable temperature coefficient. The 100 kΩ potentiometer adjusts the output voltage which has a positive TC above 1.2V, zero TC at about 1.2V and negative TC below 1.2V. This is accomplished by balancing the TC of the A2 transfer function against the complementary TC of D1.

The log amplifier of Figure 29 responds to the ratio of currents through buffer transistors Q3 and Q4. Zero temperature dependence for V_{OUT} is ensured because the TC of the A2 transfer function is equal and opposite to the TC of the logging transistors Q3 and Q4.

The wide dynamic range of the LM13600 allows easy control of the output pulse width in the Pulse Width Modulator of Figure 30.

For generating I_{ABC} over a range of 4 to 6 decades of current, the system of Figure 31 provides a logarithmic current out for a linear voltage in.

Since the closed-loop configuration ensures that the input to A2 is held equal to 0V, the output current of A1 is equal to $I_3 = -V_C/R_C$.

The differential voltage between Q1 and Q2 is attenuated by the R1, R2 network so that A1 may be assumed to be

operating within its linear range. From equation (5), the input voltage to A1 is:

$$V_{IN1} = \frac{-2kT I_3}{q I_2} = \frac{2kT V_C}{q I_2 R_C}$$

The voltage on the base of Q1 is then

$$V_{B1} = \frac{(R_1 + R_2) V_{IN1}}{R_1}$$

The ratio of the Q1 and Q2 collector currents is defined by:

$$V_{B1} = \frac{kT}{q} \ln \frac{I_{C2}}{I_{C1}} \approx \frac{kT}{q} \ln \frac{I_{ABC}}{I_1}$$

Combining and solving for I_{ABC} yields:

$$I_{ABC} = I_1 \exp \left[\frac{2(R_1 + R_2) V_C}{R_1 I_2 R_C} \right]$$

This logarithmic current can be used to bias the circuit of Figure 4 provide a temperature independent stereo attenuation characteristic.

LM13700/LM13700A Dual Operational Transconductance Amplifiers with Linearizing Diodes and Buffers

General Description

The LM13700 series consists of two current controlled transconductance amplifiers, each with differential inputs and a push-pull output. The two amplifiers share common supplies but otherwise operate independently. Linearizing diodes are provided at the inputs to reduce distortion and allow higher input levels. The result is a 10 dB signal-to-noise improvement referenced to 0.5 percent THD. High impedance buffers are provided which are especially designed to complement the dynamic range of the amplifiers.

Features

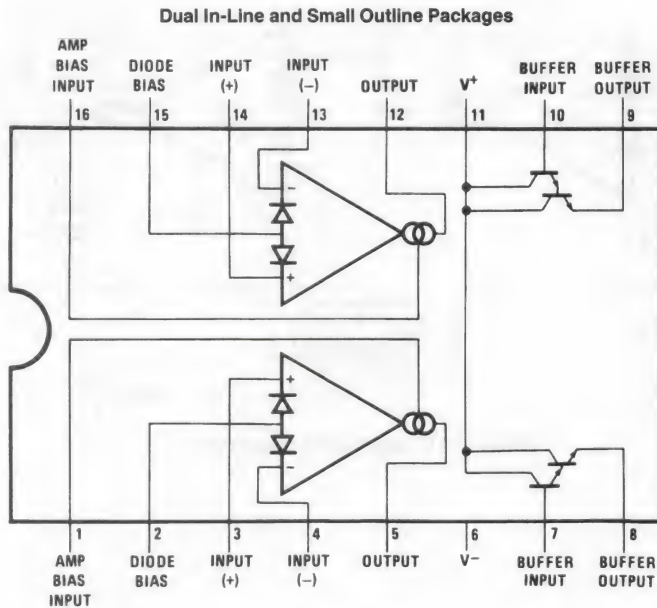

- g_m adjustable over 6 decades
- Excellent g_m linearity

- Excellent matching between amplifiers
- Linearizing diodes
- High impedance buffers
- High output signal-to-noise ratio
- Wide supply range $\pm 2V$ to $\pm 22V$

Applications

- Current-controlled amplifiers
- Current-controlled impedances
- Current-controlled filters
- Current-controlled oscillators
- Multiplexers
- Timers
- Sample-and-hold circuits

Circuit Description

The differential transistor pair Q_4 and Q_5 form a transconductance stage in that the ratio of their collector currents is defined by the differential input voltage according to the transfer function:

$$V_{IN} = \frac{kT}{q} \ln \frac{I_5}{I_4} \quad (1)$$

where V_{IN} is the differential input voltage, kT/q is approximately 26 mV at 25°C and I_5 and I_4 are the collector currents of transistors Q_5 and Q_4 respectively. With the exception of Q_3 and Q_{13} , all transistors and diodes are identical in size. Transistors Q_1 and Q_2 with Diode D_1 form a current mirror which forces the sum of currents I_4 and I_5 to equal I_{ABC} :

$$I_4 + I_5 = I_{ABC} \quad (2)$$

where I_{ABC} is the amplifier bias current applied to the gain pin.

For small differential input voltages the ratio of I_4 and I_5 approaches unity and the Taylor series of the \ln function can be approximated as:

$$\frac{kT}{q} \ln \frac{I_5}{I_4} \approx \frac{kT}{q} \frac{I_5 - I_4}{I_4} \quad (3)$$

$$I_4 \approx I_5 \approx \frac{I_{ABC}}{2} \quad (4)$$

$$V_{IN} \left[\frac{I_{ABC} q}{2kT} \right] = I_5 - I_4$$

Collector currents I_4 and I_5 are not very useful by themselves and it is necessary to subtract one current from the other. The remaining transistors and diodes form three current mirrors that produce an output current equal to I_5 minus I_4 thus:

$$V_{IN} \left[\frac{I_{ABC} q}{2kT} \right] = I_{OUT} \quad (5)$$

The term in brackets is then the transconductance of the amplifier and is proportional to I_{ABC} .

Linearizing Diodes

For differential voltages greater than a few millivolts, Equation 3 becomes less valid and the transconductance becomes increasingly nonlinear. Figure 1 demonstrates how the internal diodes can linearize the transfer function of the amplifier. For convenience assume the diodes are biased with current sources and the input signal is in the form of current I_S . Since the sum of I_4 and I_5 is I_{ABC} and the difference is I_{OUT} , currents I_4 and I_5 can be written as follows:

$$I_4 = \frac{I_{ABC}}{2} - \frac{I_{OUT}}{2}, \quad I_5 = \frac{I_{ABC}}{2} + \frac{I_{OUT}}{2}$$

Since the diodes and the input transistors have identical geometries and are subject to similar voltages and temperatures, the following is true:

$$\frac{kT}{q} \ln \frac{\frac{I_D}{2} + I_S}{\frac{I_D}{2} - I_S} = \frac{kT}{q} \ln \frac{\frac{I_{ABC}}{2} + \frac{I_{OUT}}{2}}{\frac{I_{ABC}}{2} - \frac{I_{OUT}}{2}}$$

$$\therefore I_{OUT} = I_S \left(\frac{2I_{ABC}}{I_D} \right) \text{ for } |I_S| < \frac{I_D}{2} \quad (6)$$

Notice that in deriving Equation 6 no approximations have been made and there are no temperature-dependent terms. The limitations are that the signal current not exceed $I_D/2$ and that the diodes be biased with currents. In practice, replacing the current sources with resistors will generate insignificant errors.

Applications: Voltage Controlled Amplifiers

Figure 2 shows how the linearizing diodes can be used in a voltage-controlled amplifier. To understand the input biasing, it is best to consider the 13 k Ω resistor as a current source and use a Thevenin equivalent circuit as shown in Figure 3. This circuit is similar to Figure 1 and operates the same. The potentiometer in Figure 2 is adjusted to minimize the effects of the control signal at the output.

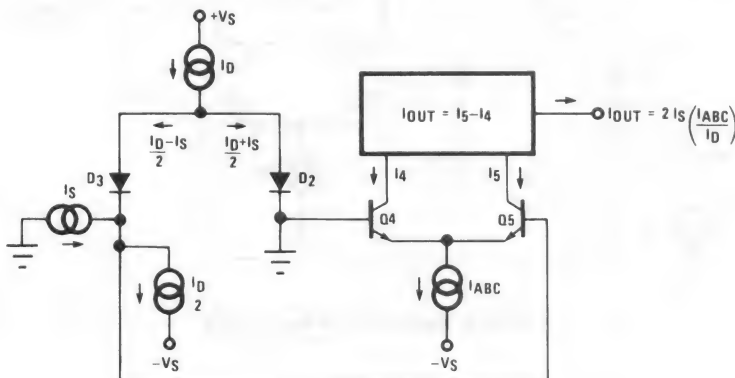

FIGURE 1. Linearizing Diodes

TL/H/7981-8

Applications: Voltage Controlled Amplifiers (Continued)

For optimum signal-to-noise performance, I_{ABC} should be as large as possible as shown by the Output Voltage vs. Amplifier Bias Current graph. Larger amplitudes of input signal also improve the S/N ratio. The linearizing diodes help here by allowing larger input signals for the same output distortion as shown by the Distortion vs. Differential Input Voltage graph. S/N may be optimized by adjusting the magnitude of the input signal via R_{IN} (Figure 2) until the output

distortion is below some desired level. The output voltage swing can then be set at any level by selecting R_L .

Although the noise contribution of the linearizing diodes is negligible relative to the contribution of the amplifier's internal transistors, I_D should be as large as possible. This minimizes the dynamic junction resistance of the diodes (r_d) and maximizes their linearizing action when balanced against R_{IN} . A value of 1 mA is recommended for I_D unless the specific application demands otherwise.

FIGURE 2. Voltage Controlled Amplifier

TL/H/7981-9

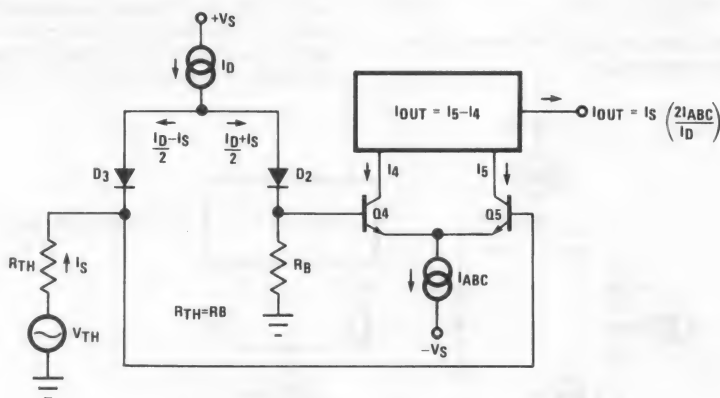

FIGURE 3. Equivalent VCA Input Circuit

TL/H/7981-10

Stereo Volume Control

The circuit of Figure 4 uses the excellent matching of the two LM13700 amplifiers to provide a Stereo Volume Control with a typical channel-to-channel gain tracking of 0.3 dB. R_P is provided to minimize the output offset voltage and may be replaced with two 510 Ω resistors in AC-coupled applications. For the component values given, amplifier gain is derived for Figure 2 as being:

$$\frac{V_O}{V_{IN}} = 940 \times I_{ABC}$$

If V_C is derived from a second signal source then the circuit becomes an amplitude modulator or two-quadrant multiplier as shown in Figure 5, where:

$$I_O = \frac{-2I_S}{I_D} (I_{ABC}) = \frac{-2I_S}{I_D} \frac{V_{IN2}}{R_C} - \frac{2I_S}{I_D} \frac{(V^- + 1.4V)}{R_C}$$

The constant term in the above equation may be cancelled by feeding $I_S \times I_D R_C / 2(V^- + 1.4V)$ into I_O . The circuit of Figure 6 adds R_M to provide this current, resulting in a four-quadrant multiplier where R_C is trimmed such that $V_O = 0V$ for $V_{IN2} = 0V$. R_M also serves as the load resistor for I_O .

FIGURE 4. Stereo Volume Control

FIGURE 5. Amplitude Modulator

TL/H/7981-12

Stereo Volume Control (Continued)

TL/H/7981-13

FIGURE 6. Four-Quadrant Multiplier

Noting that the gain of the LM13700 amplifier of Figure 3 may be controlled by varying the linearizing diode current I_D as well as by varying I_{ABC} , Figure 7 shows an AGC Amplifier using this approach. As V_O reaches a high enough amplitude ($3V_{BE}$) to turn on the Darlington transistors and the linearizing diodes, the increase in I_D reduces the amplifier gain so as to hold V_O at that level.

Voltage Controlled Resistors

An Operational Transconductance Amplifier (OTA) may be used to implement a Voltage Controlled Resistor as shown in Figure 8. A signal voltage applied at R_X generates a V_{IN}

to the LM13700 which is then multiplied by the g_m of the amplifier to produce an output current, thus:

$$R_X = \frac{R + R_A}{g_m R_A}$$

where $g_m \approx 19.2 I_{ABC}$ at 25°C . Note that the attenuation of V_O by R and R_A is necessary to maintain V_{IN} within the linear range of the LM13700 input.

Figure 9 shows a similar VCR where the linearizing diodes are added, essentially improving the noise performance of the resistor. A floating VCR is shown in Figure 10, where each "end" of the "resistor" may be at any voltage within the output voltage range of the LM13700.

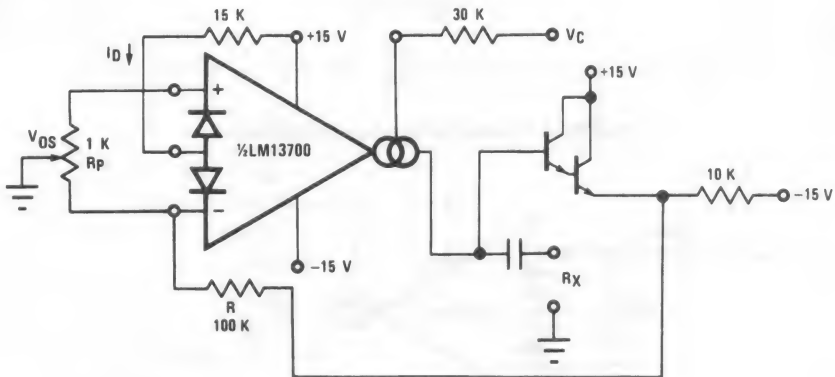

FIGURE 9. Voltage Controlled Resistor with Linearizing Diodes

TL/H/7981-16

Voltage Controlled Filters

OTA's are extremely useful for implementing voltage controlled filters, with the LM13700 having the advantage that the required buffers are included on the I.C. The VC Lo-Pass Filter of Figure 11 performs as a unity-gain buffer amplifier at frequencies below cut-off, with the cut-off frequency being the point at which X_C/g_m equals the closed-loop gain of (R/R_A). At frequencies above cut-off the circuit provides a single RC roll-off (6 dB per octave) of the input signal amplitude with a -3 dB point defined by the given equation, where g_m is again $19.2 \times I_{ABC}$ at room temperature. Figure

12 shows a VC High-Pass Filter which operates in much the same manner, providing a single RC roll-off below the defined cut-off frequency.

Additional amplifiers may be used to implement higher order filters as demonstrated by the two-pole Butterworth Lo-Pass Filter of Figure 13 and the state variable filter of Figure 14. Due to the excellent g_m tracking of the two amplifiers, these filters perform well over several decades of frequency.

FIGURE 18. Single Amplifier VCO

Figure 18 shows how to build a VCO using one amplifier when the other amplifier is needed for another function.

Additional Applications

Figure 19 presents an interesting one-shot which draws no power supply current until it is triggered. A positive-going trigger pulse of at least 2V amplitude turns on the amplifier through R_B and pulls the non-inverting input high. The amplifier regenerates and latches its output high until capacitor C charges to the voltage level on the non-inverting input. The output then switches low, turning off the amplifier and discharging the capacitor. The capacitor discharge rate is speeded up by shorting the diode bias pin to the inverting input so that an additional discharge current flows through D_1 when the amplifier output switches low. A special feature of this timer is that the other amplifier, when biased from V_O , can perform another function and draw zero stand-by power as well.

TL/H/7981-26

FIGURE 19. Zero Stand-By Power Timer

Additional Applications (Continued)

The operation of the multiplexer of *Figure 20* is very straightforward. When A1 is turned on it holds V_O equal to V_{IN1} and when A2 is supplied with bias current then it controls V_O . C_C and R_C serve to stabilize the unity-gain configuration of amplifiers A1 and A2. The maximum clock rate is limited to about 200 kHz by the LM13700 slew rate into 150 pF when the $(V_{IN1} - V_{IN2})$ differential is at its maximum allowable value of 5V.

The Phase-Locked Loop of *Figure 21* uses the four-quadrant multiplier of *Figure 6* and the VCO of *Figure 18* to produce a PLL with a $\pm 5\%$ hold-in range and an input sensitivity of about 300 mV.

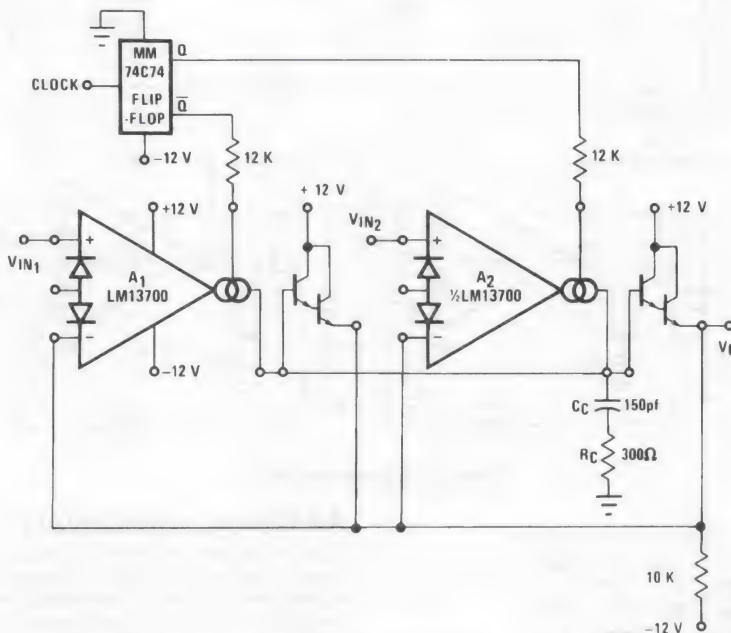

FIGURE 20. Multiplexer

TL/H/7981-27

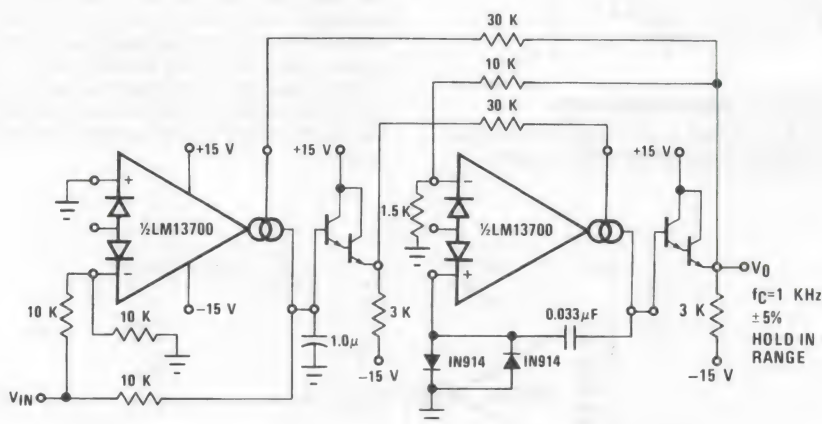

FIGURE 21. Phase Lock Loop

TL/H/7981-28

Additional Applications (Continued)

The Schmitt Trigger of *Figure 22* uses the amplifier output current into R to set the hysteresis of the comparator; thus $V_H = 2 \times R \times I_B$. Varying I_B will produce a Schmitt Trigger with variable hysteresis.

FIGURE 22. Schmitt Trigger

TL/H/7981-29

Figure 23 shows a Tachometer or Frequency-to-Voltage converter. Whenever A1 is toggled by a positive-going input, an amount of charge equal to $(V_H - V_L) C_f$ is sourced into C_f and R_f . This once per cycle charge is then balanced by the current of V_O/R_f . The maximum F_{IN} is limited by the amount of time required to charge C_f from V_L to V_H with a current of I_B , where V_L and V_H represent the maximum low and maximum high output voltage swing of the LM13700. D1 is added to provide a discharge path for C_f when A1 switches low. The Peak Detector of *Figure 24* uses A2 to turn on A1 whenever V_{IN} becomes more positive than V_O . A1 then charges storage capacitor C to hold V_O equal to V_{IN} PK. Pulling the output of A2 low through D1 serves to turn off A1 so that V_O remains constant.

FIGURE 23. Tachometer

TL/H/7981-30

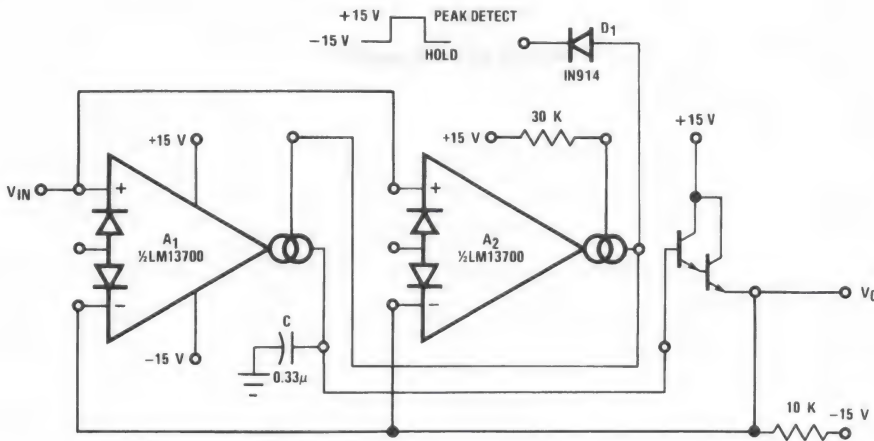

FIGURE 24. Peak Detector and Hold Circuit

TL/H/7981-31

Additional Applications (Continued)

The Ramp-and-Hold of Figure 26 sources I_B into capacitor C whenever the input to A1 is brought high, giving a ramp-rate of about 1V/ms for the component values shown.

The true-RMS converter of Figure 27 is essentially an automatic gain control amplifier which adjusts its gain such that the AC power at the output of amplifier A1 is constant. The output power of amplifier A1 is monitored by squaring amplifier A2 and the average compared to a reference voltage with amplifier A3. The output of A3 provides bias current to the diodes of A1 to attenuate the input signal. Because the output power of A1 is held constant, the RMS value is constant and the attenuation is directly proportional to the RMS value of the input voltage. The attenuation is also proportional to the diode bias current. Amplifier A4 adjusts the ratio of currents through the diodes to be equal and therefore the voltage at the output of A4 is proportional to the RMS value of the input voltage. The calibration potentiometer is set such that V_O reads directly in RMS volts.

FIGURE 25. Sample-Hold Circuit

TL/H/7981-32

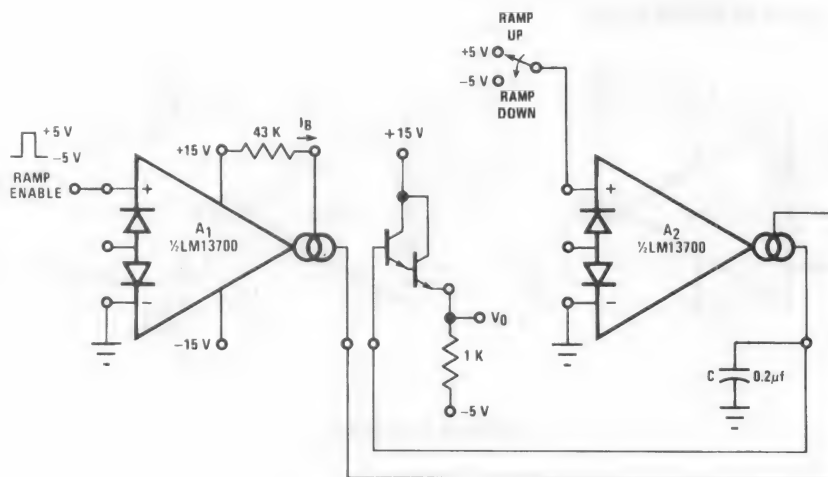

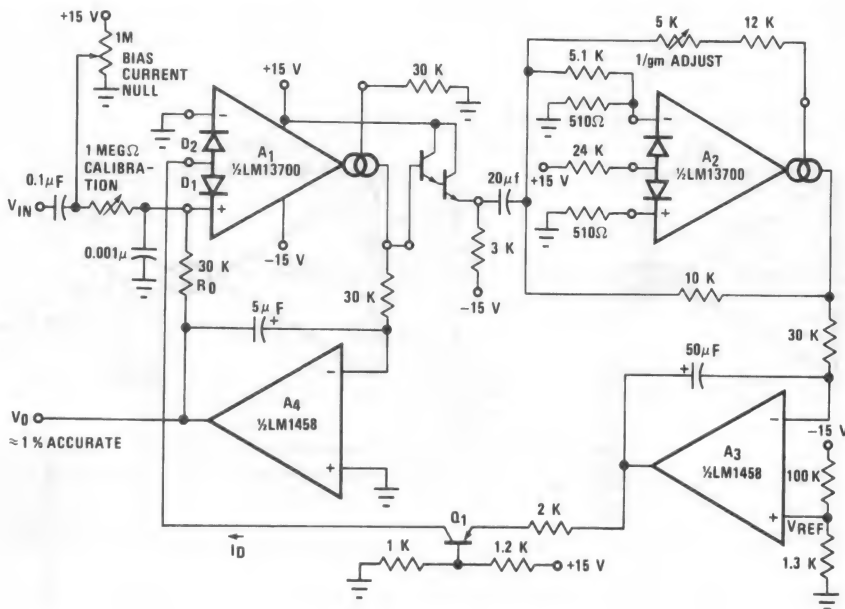

FIGURE 26. Ramp and Hold

TL/H/7981-33

Additional Applications (Continued)

TL/H/7981-34

FIGURE 27. True RMS Converter

The circuit of Figure 28 is a voltage reference of variable Temperature Coefficient. The 100 kΩ potentiometer adjusts the output voltage which has a positive TC above 1.2V, zero TC at about 1.2V, and negative TC below 1.2V. This is accomplished by balancing the TC of the A2 transfer function against the complementary TC of D1.

The wide dynamic range of the LM13700 allows easy control of the output pulse width in the Pulse Width Modulator of Figure 29.

For generating I_{ABC} over a range of 4 to 6 decades of current, the system of Figure 30 provides a logarithmic current out for a linear voltage in.

Since the closed-loop configuration ensures that the input to A2 is held equal to 0V, the output current of A1 is equal to $I_3 = -V_C/R_C$.

The differential voltage between Q1 and Q2 is attenuated by the R1,R2 network so that A1 may be assumed to be

operating within its linear range. From equation (5), the input voltage to A1 is:

$$V_{IN1} = \frac{-2kT I_3}{q I_2} = \frac{-2kT V_C}{q I_2 R_C}$$

The voltage on the base of Q1 is then

$$V_{B1} = \frac{(R_1 + R_2) V_{IN1}}{R_1}$$

The ratio of the Q1 and Q2 collector currents is defined by:

$$V_{B1} = \frac{kT}{q} \ln \frac{I_{C2}}{I_{C1}} \approx \frac{kT}{q} \ln \frac{I_{ABC}}{I_1}$$

Combining and solving for I_{ABC} yields:

$$I_{ABC} = I_1 \exp \frac{2(R_1 + R_2) V_C}{R_1 I_2 R_C}$$

This logarithmic current can be used to bias the circuit of Figure 4 to provide temperature independent stereo attenuation characteristic.

LM18272 Dual Power Operational Amplifier

General Description

The LM18272 is a dual operational amplifier capable of low output saturation voltages at high output currents. It is suitable for driving small motors and solenoids in both linear and saturated modes of operation. Thermal limiting and wide differential input voltage range reduce external protection requirements.

Features

- Full output swing at ± 500 mA
- Wide operating, power supply range (4.5V to 24V)
- Internally compensated for unity gain
- Thermal shutdown protected
- High differential input voltage
- Input CM range includes ground
- Dual Op-Amp in 8-lead Mini Dip

LMC660AM / LMC660AI / LMC660C CMOS Quad Operational Amplifier

General Description

The LMC660 CMOS Quad operational amplifier is ideal for operation from a single supply. It is fully specified for operation from +5V to +15V and features rail-to-rail output swing in addition to an input common-mode range that includes ground. Performance limitations that have plagued CMOS amplifiers in the past are not a problem with this design. Input V_{OS} , drift, and broadband noise as well as voltage gain into realistic loads (2 k Ω and 600 Ω) are all equal to or better than widely accepted bipolar equivalents. This chip is built with National's advanced Double-Poly Silicon-Gate CMOS process.

Features

- Rail-to-rail output swing
 - Specified for 2 k Ω and 600 Ω loads
 - High voltage gain
 - Low input offset voltage
 - Low offset voltage drift
 - Ultra low input bias current
 - Input common-mode includes GND
 - Operation guaranteed from +5V to +15V
 - $I_{SS} = 375 \mu A/\text{amplifier}$; independent of V^+
 - Low distortion
 - Slew rate
 - Insensitive to latch-up
- 126 dB
3 mV max
1.3 $\mu V/^{\circ}C$
40 fA
0.01% at 10 kHz
1.1 V/ μs

Note 1: Applies to both single supply and split supply operation. Continuous short circuit operation at elevated ambient temperature and/or multiple Op Amp shorts can result in exceeding the maximum allowed junction temperature of 150°C.

Note 2: The junction-to-ambient thermal resistance of the molded plastic DIP (N) is 75°C/W., the molded plastic SO (M) package is 105°C/W., and the cavity DIP (D) package is 92°C/W. All numbers apply for packages soldered directly into a PC board.

Note 3: Unless otherwise specified, all limits guaranteed for $T_A = T_J = 25^\circ\text{C}$. **Boldface** limits apply at the temperature extremes. $V^+ = 5\text{V}$, $V^- = 0\text{V}$, $V_{CM} = 1.5\text{V}$, $V_O = V^+/2$, and $R_L > 1 \text{ M}\Omega$ unless otherwise specified.

Note 4: These limits are guaranteed and are used in calculating outgoing AQL.

Note 5: These limits are guaranteed, but are not used in calculating outgoing AQL.

Note 6: $V^+ = 15\text{V}$, $V_{CM} = 7.5\text{V}$ and R_L connected to 7.5V. For Sourcing tests, $7.5\text{V} \leq V_O \leq 11.5\text{V}$. For Sinking tests, $2.5\text{V} \leq V_O \leq 7.5\text{V}$.

Note 7: $V^+ = 15\text{V}$. Connected as Voltage Follower with 10V step input. Number specified is the slower of the positive and negative slew rates.

Note 8: Input referred. $V^+ = 15\text{V}$ and $R_L = 10 \text{ k}\Omega$ connected to $V^+/2$. Each amp excited in turn with 1 kHz to produce $V_O = 13 \text{ V}_{PP}$.

Note 9: The specifications in the Design Limit column reflect the true performance of the part, while those in the Tested Limit column are degraded to allow for the unavoidable inaccuracies involved in cost-effective high-speed automatic testing.

LMC668A/LMC668 Chopper Stabilized Operational Amplifier

General Description

The LMC668 is a high performance versatile chopper-stabilized amplifier with low input offset voltage. This low offset is achieved through a nulling scheme that provides continuous error correction. A nulling amplifier alternately nulls itself and the main amplifier. Two external capacitors are used to store the correcting voltages on the amplifier nulling inputs. The LMC668 has exceptionally low offset drift over time and temperature. The nulling circuit also provides for very high open loop gain, CMRR, and PSRR at low frequencies.

The clock oscillator and all the other control circuitry are completely self contained. The 14-pin version has an Internal/External Clock select pin and an External Clock In pin for use in applications requiring synchronized or special chopping frequencies. The 8-pin version does not allow for an external clock or the output clamp. Both versions are pin compatible replacements for the ICL7650 series of parts.

Features

- Low input offset voltage
- High gain, CMRR and PSRR
- Low offset voltage drift with time and temperature

- Low DC input bias current
- Low intermodulation effects

Key Specifications

- Input offset voltage $< \pm 5 \mu\text{V}$
- DC input bias current $< 60 \text{ pA}$
- Large signal voltage gain $> 10^6 \text{ V/V}$
- Common mode rejection ratio $> 120 \text{ dB}$
- Power supply rejection ratio $> 120 \text{ dB}$
- Internal chopping frequency Typ 200 Hz

Note 1: Absolute Maximum Ratings indicate limits beyond which damage to the device may occur. DC and AC electrical specifications do not apply when operating the device beyond its specified operating ratings.

Note 2: To avoid possible destructive latchup, currents greater than 100 μA should not be forced into the input pins.

Note 3: The maximum allowable power dissipation must be derated at elevated temperatures and is dictated by T_{JMAX} , Θ_{JA} , and ambient temperature, T_A . The maximum allowable power dissipation at any temperature is $P_D = (T_{JMAX} - T_A)/\Theta_{JA}$ or the number given in the Absolute Maximum Ratings, whichever is less. Θ_{JA} is typically 120°C/W for the J package and 140°C/W for the N package.

Note 4: Human body model, 100 pF discharged through a 1.5 k Ω resistor.

Note 5: Specifications in the "Typical" column are at 25°C and represent the most likely parametric norm.

Note 6: Tested and guaranteed to National's AOQL (Average Outgoing Quality Level).

Note 7: Guaranteed and not 100% production tested. These limits are not used to calculate outgoing quality levels.

Note 8: See Output Clamp discussion in Application Hints.

THEORY OF OPERATION

Figure 1 shows a simplified block diagram of the LMC668's analog signal path. The circuit effectively consists of two amplifiers, some MOS switches, and a pair of external capacitors. The "main amplifier" is a conventional MOS operational amplifier and is connected to the external feedback components. This amplifier is always active. The "null amplifier" has its inverting input connected to the main amplifier's inverting input. The null amplifier's non-inverting input is switched between the main amplifier's two inputs. Each amplifier also has an additional input pin that can be used to adjust V_{OS} .

In operation, the null amplifier's inputs are first shorted together, and its output is connected to its V_{OS} input. This creates a negative feedback loop that adjusts the input V_{OS}

to zero. When switches A' and B' are opened, the correction voltage at the V_{OS} input is stored by capacitor C_A , holding the null amplifier offset voltage at zero. Switch B is then closed, shorting the main amplifier's non-inverting input to the null amplifier's non-inverting input. Since the main amplifier is enclosed in the external feedback loop, its two inputs should ideally be at the same voltage. Any voltage difference between the main amplifier's inputs will be amplified by the nullifying amplifier and applied to the main amp's V_{OS} adjust pin. The closed loop system reaches equilibrium when the main amplifier's input V_{OS} equals zero. The correction voltage for the main amplifier is stored on C_B , and the entire process repeats at the chopping frequency (around 200 Hz).

⊗ SWITCH CLOSED WHEN LOGIC IS HIGH

FIGURE 1. Block Diagram of LMC668 Analog Signal Path

TL/H/9128-6

Application Hints (Continued)

Figure 2 shows a simplified schematic of the block diagram in Figure 1. Note that transistor P1 serves as the inverting input for both the main amplifier and the null amplifier. Note also that the "back gate" substrate connections on transistors N1 and N2 are the V_{OS} adjust inputs. Increasing the back gate voltage on these transistors increases the channel conductivity, but to a lesser degree than would be caused by an equivalent voltage change at the "normal" gate.

INTERMODULATION

An ideal operational amplifier has infinite gain at all frequencies, so that when feedback is applied, the voltage differential between the two inputs will be zero. A real amplifier has finite gain that decreases with increasing frequency, resulting in a small voltage across the inputs that increases with signal frequency. In a typical chopper-stabilized amplifier, the ac voltage is modulated by the chopping frequency, creating spurious output signals at sum and difference frequencies of the input frequency, the chopping frequency, and their harmonics. The LMC668 combats this problem by injecting a compensation signal into the nulling amplifier. This compensation substantially reduces the levels of intermodulation components at the amplifier output.

OUTPUT CLAMP

When an operational amplifier is overdriven and clips, the feedback loop opens, and the input differential voltage can

become quite large. This voltage is equivalent to a large input offset voltage, so the LMC668's offset correction circuitry attempts to compensate for it, and the external capacitors are eventually charged to rather high voltages before the correction circuit saturates. When the overdrive is removed the capacitors can't be immediately discharged so the circuit takes a long time to recover from the saturated condition.

The 14-pin version of the LMC668 includes a circuit whose purpose is to prevent excessive overdrive recovery time by introducing a current path from the amplifier output to the inverting input. This current path is inactive until the output voltage approaches the supply voltage. Just before the onset of clipping, the current path becomes active and clamps the output voltage before it saturates. Since the clamping action occurs within the feedback loop, the input differential voltage will remain near zero volts and long recovery times are eliminated. The clamp circuit is brought into operation by connecting the clamp pin (9) to the inverting input (pin 4). For best performance, the parallel combination of the feedback resistors should be 100 k Ω or higher. A small feedback capacitor (≈ 10 pF) may be needed to reduce clamp oscillations.

The only disadvantage to the use of the clamp is a slight reduction in output voltage swing (see Typical Performance curves).

Application Hints (Continued)

TL/H/9128-8

FIGURE 3. Using External Clock (14-pin LMC668 only). For operation with internal clock, leave pins 13 and 14 open.

THERMOELECTRIC EFFECTS

When dissimilar metals come into contact with one another, thermocouples are created that generate dc error voltages. To reduce the effects of thermocouples, temperatures throughout the sensitive parts of the system should be as similar as possible. Circuitry should be enclosed to limit air movement, junctions with high thermoelectric coefficients should be avoided, and power dissipation should be minimized as much as possible to avoid thermal gradients.

CLOCK CONSIDERATIONS

The internal clock in the LMC668 is set to oscillate around 400 Hz. This signal is available at pin 12 of the 14-pin LMC668. The actual chopping rate is half of the clock frequency. The 14-pin version of the device provides the option of using a different clock frequency from an external source. To do this the INT/EXT pin must be tied to V^- to disable the internal clock (Figure 3). This pin has an internal pull-up, so it may be left open when the internal clock is used. At frequencies below 500 Hz, the external clock's duty cycle is not critical, but above this frequency, a 60% to 80% positive duty cycle will give better results since the null storage capacitors (C_A and C_B) are charged only on the positive half of the clock waveform. A positive duty cycle ensures that the capacitors will be fully charged and any transients will have settled before they are disconnected from the charging circuitry. The maximum recommended clock frequency is approximately 1 kHz. Higher frequencies should be avoided because the offset voltage is degraded at fast chopping rates. The external clock signal should swing between ground and V^+ for supply voltages up to $\pm 6V$, and between V^+ and $V^+ - 6V$ for higher supplies. Voltages outside of this range may cause damage to the IC.

EXTERNAL CAPACITORS

C_A and C_B should be connected from the C_A and C_B pins to the C_R pin. Where possible, the outside foil leads should be connected to C_R . If the internal 200 Hz clock is used, the capacitors should be $0.1 \mu F$. The optimum capacitance varies inversely with chopping frequency. Good quality film capacitors (mylar, polypropylene, polystyrene, polycarbonate, etc.) will give best results. Capacitors with low dielectric absorption (polypropylene and polystyrene) yield the fastest initial settling and turn-on performance. Ceramic capacitors may be adequate in some applications, but these may require several seconds to settle to very low offset values.

LOAD IMPEDANCE

The LMC668 output stage has a relatively high (18 k Ω) output impedance, so the load impedance will have a strong influence on amplifier performance. This is illustrated in the Typical Performance Curves showing open-loop gain for two different load resistors. It is recommended that the load impedance be kept above 10 k Ω to avoid drastic loss of gain, especially at high frequencies. This load resistance will result in a smooth first-order rolloff in the open-loop gain from 0.1 Hz to 2 MHz, with phase errors under 10° in the transition region where the main amplifier takes over from the null amplifier.

LEAKAGE CURRENTS AND INPUT GUARDING

When the low input bias currents of the LMC668 are essential to an application, it is important to take special steps to reduce external sources of leakage currents. Circuit boards must be thoroughly cleaned with appropriate solvents and blown dry with compressed air, and the cleaned traces should be coated with epoxy or silicone rubber to prevent contamination.

Leakage currents due to circuit board traces at supply potentials near the input pins can be excessive for some applications, and these can be minimized by using a guard ring around the input pins. This ring should be tied to a voltage that is near the voltage on the input pins. It will absorb most of the leakage currents from high potential pins and traces.

OUTPUT GLITCHES

The CMOS switches in the LMC668, like all analog switches, produce transients when they are turned on or off. These transients are minimized by careful balancing of the internal switches, but they will still couple to the amplifier output. The transients can be minimized by keeping source impedances low. Input referred glitches on the order of 100 μV are typical with a source impedance of 10 k Ω and $A_v = 1000$. Glitch amplitude increases with higher source resistance and decreases when the clamp circuit is used. At low gains ($A_v < 10$), output glitch amplitude is not as strongly dependent on gain. Typical output glitch amplitudes for $R_1 = R_2 = 100 \text{ k}\Omega$ (Figure 3), are 100 mV to 150 mVp-p.

LMC669 Auto-Zero

General Description

The LMC669 uses sampled-data techniques to reduce the input offset voltage (V_{OS}) of an amplifier or system to approximately $5 \mu\text{V}$. A four-stage comparator samples the summing node of an inverting-amplifier and generates a correction voltage that is applied to the amplifier's non-inverting input. The offset correction is independent of time, temperature, and supply voltage, and requires no initial or periodic user offset adjustments.

The user may also adjust clock frequency, sample rate, and the correction voltage's step size and magnitude.

The Auto-Zero operates on supply voltages of $\pm 8\text{V}$ to $\pm 20\text{V}$ with a quiescent current of 3 mA .

The use of the LMC669 does not limit the performance of the amplifier it is used with. Full use of the gain-bandwidth product, slew rate, and DC gain is retained.

The LMC669 can be used as a precision comparator with a latched, open drain output, or as a low-offset inverting operational amplifier for low-speed applications.

Features

- 5 microvolts typical offset voltage
- Temperature independent offset correction
- Internal or external clocking
- Automatic and continuous offset voltage correction
- High voltage CMOS—up to $\pm 20\text{V}$ supplies

Note 1: Absolute Maximum Ratings indicate limits beyond which damage to the device may occur. DC and AC electrical specifications do not apply when operating the device beyond its specified operating conditions.

Note 2: All voltages are with respect to AGND.

Note 3: This input current will exist only when an input is driven to a voltage greater than $(V^+ + 0.2V)$ or less than $-0.2V$. It is due to internal diode clamps at the inputs turning on. If the current is limited to 20 mA, the overdrive will not be harmful to the LMC669.

Note 4: The typical junction-to-ambient thermal resistance (θ_{JA}) of the 16 pin J package is $80^\circ C/W$.

Note 5: If input currents are limited, input voltages may be driven beyond these limits and the device will still be functional. The comparator output will be correct as long as the voltage on either the INREF pin or the two input IN1 & IN2 pins is between $-200 mV$ and $+2V$.

Note 6: Typical values are at $25^\circ C$ and represent most likely parametric norm.

Note 7: Guaranteed and 100% tested.

Note 8: Guaranteed, but not 100% production tested. These limits are not used to calculate outgoing quality levels.

Note 9: The LMC669CD exhibits a warm-up drift of approximately $3 \mu V$ to $5 \mu V$ in the negative direction. There are two factors that work together to cause this. Firstly, as the die becomes warm, a temperature gradient forms between pin 2 and pins 1 and 16. Secondly, a thermocouple is created between the metal of the leadframe and the metal of the wire (usually copper) used to connect the IC to a circuit. It takes about 6 minutes for the drift to stabilize. The N and M packages do not exhibit this drift because their leadframes are 90% copper.

*These pins must be connected as shown to ensure compatibility with future parts.

Pin Description LMC669 Numbers in () are for 16-pin package

Pin	Description
IN1, IN2 1, 20 (1, 16)	These are the inputs to the Auto Zero's comparator. They should be tied together and connected to the summing node of the host operational amplifier (op amp). One set of inputs, either IN1 and IN2 or INREF, must be between +2 volts and ground while the other can go to V^+ (also refer to notes 3 and 5).

Pin	Description
INREF 2 (2)	This is the input for the comparator's reference voltage. Correction of V_{OS} is accomplished by connecting this pin to a good clean system ground of its own. One set of inputs, either IN1 and IN2 or INREF, must be between +2 volts and ground while the other can go to V^+ (also refer to notes 3 and 5).

Pin Description 16-pin LMC669 (Continued)

Pin	Description
AGND 3, 19 (3, 15)	These act to shield the IN1, IN2, and INREF connections from stray capacitance and leakage which could degrade the part's performance. They should be connected to a high quality ground.
DGND 18 (14)	Provides a separate ground for the internal digital circuitry to prevent noise from corrupting the comparator inputs. It should have its own ground connection.
COMPOUT 5 (4)	This is the latched output from the internal comparator. It is an open drain which can be left unconnected if not needed. Its response time is equal to the sample rate's period. The rise time, from 10% to 90%, is nominally 500 ns with a 10 k Ω pull-up resistor. The output is typically capable of swinging from +0.25 (at 1 mA) to +25 volts.
OUTREF 6 (5)	Output reference; for proper integrator operation this input should be connected to a good system ground, such as the ground to which INREF is connected.
OUTPUT 8 (7)	This is the LMC669's integrator output. It can swing from -12 to +12 volts in 0.2 volt steps with a ≥ 10 K Ω load and no external integrating capacitor.
CAP 7 (6)	When a capacitor is used to decrease the correction voltage's step size, it is connected between CAP and OUTPUT. It parallels an internal 10 pF capacitor.
CLK 12 (9)	External clock input/internal adjust. The frequency of the internal clock (nominally 100 kHz) may be reduced with an external capacitor or an external clock connected to the CLK input. The logic thresholds for this input are 4 volts for a logic high and 1 volt for logic low. The internal clock can be stopped by applying a logic high, through a diode, to the CLK input. When a logic low is applied to the diode, the internal clock runs freely. (See Figure 3)
RESET 13 (10)	Comparator reset. At power-up, or when RESET is pulled low during normal operation, the Auto Zero will run at its fastest sample rate. This allows for the quickest V_{OS} nulling.
4	Leave this pin unconnected.
9, 10	Connect these pins together.
14	Connect to analog ground.

Pin	Description
T1, T2 16, 15 (12, 11)	These pins select one of five clock divider ratios. The ratio, hence the sample rate can be changed by applying V^+ or ground to T1 and T2. The ratio chosen by these inputs is valid after the comparator's output changes state; i.e., a zero-crossing between the offset and correction voltage has taken place. These inputs can also be changed at any time to modify the LMC669's sample rate. Use the table below to determine the reduction in the clock's frequency f_{or} each combination of T1 and T2.

T1	T2	RESET	\div
X	X	0	1
1	1	1	4
1	0	1	16
0	1	1	128
0	0	1	1024

V^+, V^-
17, 11
(13, 8)

Positive and negative power supply inputs. Typical supply voltages are ± 15 volts, but operation will take place from ± 8 to ± 20 volts. Power supply current is typically 3 mA. Bypass capacitors (0.01 \sim 0.1 μ F) should be connected to the power supply pins.

Application Hints

1.0 INTRODUCTION

In its standard application shown in *Figure 1*, the LMC669 continuously samples the summing node of an inverting amplifier and generates a correction voltage for the amplifier's non-inverting input, nulling the amplifier's input offset voltage (V_{OS}) to 5 μ V. The offset correction is independent of time, temperature, and supply voltage. The LMC669 eliminates the need for initial or periodic offset adjustments, compensates for V_{OS} drift due to temperature changes, allows the use of greater DC gain, and increases immunity to changes in power supply voltages.

At the input of the LMC669 is a sampled-data differential comparator with very low offset voltage. When the comparator samples the summing node voltage and determines that it is not at ground, the LMC669's output generates a small voltage step in the opposite direction of the error. The size of the step and the sample rate are user-selectable. The correction voltage continues to step up or down until the summing node is within the V_{OS} of the LMC669—typically 5 μ V. At this point the Auto Zero continues to monitor the summing node and perform any needed corrections. An internal divider generates five different sampling rates for any given clock frequency.

The only external parts needed for V_{OS} correction of most amplifiers are two resistors and one capacitor. Since the capacitor is in the feedback loop of an integrator, it should be a low leakage type (polycarbonate, polypropylene, polystyrene, mylar, etc.). The tolerance of the resistors and capacitor is not critical (10% components are satisfactory).

Application Hints (Continued)

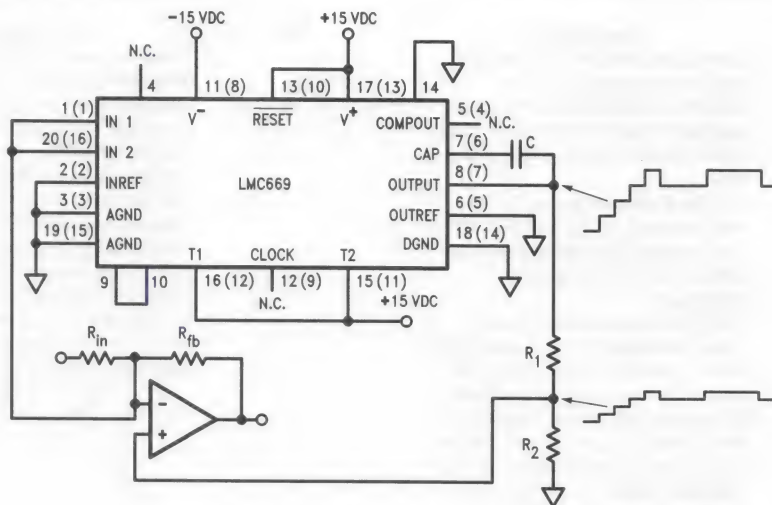

FIGURE 1. Typical Application

TL/H/8561-5

1.1 CIRCUIT OPERATION

At the heart of the LMC669 is a four-stage precision sampled-data comparator, shown in Figure 2. The circuit operates by successively zeroing the offset of each stage, resulting in a very high gain amplifier with extremely low input offset voltage.

After a comparator decision is made, the latch is enabled and holds the comparator's output state. At the same time this state appears at COMPOUT. The latch also generates a $\pm 1V$ signal that charges capacitor C_1 to $\pm 1V$. C_1 's charge is then transferred to the integrator's feedback capacitor C_2 . Since C_2 is five times larger than C_1 , a 200 mV step will appear at the integrator's output. Further reduction of the step size is possible with an external capacitor connected in parallel with C_2 (between OUTPUT and CAP). The integrator output is then attenuated by a resistive divider network before being applied to the external op amp's non-inverting input, completing the offset correction loop.

1.2 CLOCKS

In order to control the events that take place in the LMC669, an internal Schmitt trigger oscillator generates a 100 kHz clock. This oscillator's frequency can be lowered by connecting a capacitor between the CLK input and ground as in Figure 3c. It can also be overridden by applying an external clock source (≤ 100 kHz) to the CLK input (Figure 3a). Further, the clock can be halted with a diode connected as shown in Figure 3(b).

The clock signal drives the input of the divider (See Figure 2). Depending on the logic levels at inputs T1, T2, and RESET, the clock can be divided by five different ratios (1, 4, 16, 128, and 1024). The output of the divider triggers the sequencer which controls the auto-zero function.

When the LMC669 is powered-up or reset the internal divider automatically divides by one. This allows the Auto-Zero to operate at maximum sampling rate so that large initial offsets can be rapidly corrected. When the comparator toggles for the first time, this indicates that input null has been achieved and that maximum sample rate is no longer required. The latch then switches the divider from $\div 1$ to the ratio programmed via T1 and T2. By employing this "two speed" approach the device can move quickly to handle turn-on transients and then shift to the optimum "gear" for long term offset correction. It is also possible to return to the maximum sample rate via the RESET input so that non-power-up transients can be dealt with as well.

1.3 INPUT RANGE

The IN1, IN2, and INREF inputs can accept signal levels between 0 and +2 V. However, as long as both IN1 and IN2, or INREF, is kept between 0 and 2V the other input (or inputs) can be taken to V^+ and, if input current limiting (≤ 20 mA) is provided, to V^- . In most auto-zero applications IN1 and IN2 will be able to go to these extended limits since INREF will normally be grounded.

2.0 APPLICATION CIRCUITS

The most general application of the Auto-Zero is offset correction of an inverting op amp as shown in *Figure 1*. The example below shows how the integration capacitor and the resistor divider are chosen.

Determine the maximum expected offset voltage from the op amp characteristics and the requirements of the overall system. The correction voltage swing capability should be greater than or equal to this value. Also select the minimum system resolution and the time that can be allowed to null the initial offset. These will determine the correction voltage step size. The magnitude of the correction voltage (V_{corr}) and the step size (dv) are defined according to equations 1 and 2:

$$\text{Correction voltage} = V_{corr} = V_{out} \frac{R_2}{R_1 + R_2} \quad (1)$$

V_o is typically $\pm 12V$ for $\pm 15V$ supplies.

$$R_2 = \frac{R_1 V_{corr}}{(V_o - V_{corr})} \quad (1a)$$

$$= \frac{10K V_{corr}}{(12 - V_{corr})}$$

for $R_1 = 10 k\Omega$ (For proper operation $R_1 + R_2$ should be greater than $10 k\Omega$.)

$$\text{step size} = dv = 1.0V \left(\frac{C_1}{C_2 + C_1} \right) \left(\frac{R_2}{R_1 + R_2} \right) \quad (2)$$

$$C = \frac{C_1 R_2}{dv (R_1 + R_2)} - C_2 \quad (2a)$$

with $C_1 = 2 pF$, $C_2 = 10 pF$, R_1 and R_2 from Eq. 1a. C_1 and C_2 are internal.

A further consideration regarding the selection of step size is resolution: the magnitude of the smallest significant signal. In the case of nulling the V_{os} of an op amp used with a digital-to-analog converter (DAC) the smallest signal is the voltage produced by the least-significant bit (LSB). Therefore, the correction voltage's step size would need to be much smaller than the magnitude of the DAC's LSB in order to retain the DAC's desired resolution.

Finally, for proper operation, the sampling period should be longer than the amplifier's settling time. $10 \mu s$ or more should be adequate for most contemporary amplifiers.

DESIGN EXAMPLE

As an example, assume that the offset of the op amp in *Figure 1* is expected to be no more than $15 mV$ and the system can tolerate a $1 \mu V$ square wave at a rate equal to the internal clock. Begin by using R_1 and R_2 to set the maximum correction voltage to $15 mV$. The LMC669's output can swing to ± 12 volts with a $10 K\Omega$ load and a ± 15 volt power supply. R_1 and R_2 should be chosen to reduce this to $15 mV$:

$$R_2 = \frac{R_1 V_{corr}}{V_o - V_{corr}}$$

$$= \frac{(10K)(0.015)}{(12 - 0.015)}$$

$$= 12.5\Omega \approx 13\Omega$$

for $\pm 15V$ supplies and $R_1 = 10K$.

Now choose C , the integrator's external feedback capacitor, to set the final step size to $1 \mu V$. Using equation (2a):

$$C = \frac{C_1 R_2}{dv(R_1 + R_2)} - C_2$$

with $R_1 = 10 k\Omega$, $R_2 = 13\Omega$, $C_1 = 2 pF$,
and $C_2 = 10 pF$, yields

$$C \approx 2500 pF$$

The null time for this example, with an amplifier offset of $15 mV$, step size of $1 \mu V$, and initial sample rate of $100 kHz$, is

$$\text{Null time} = \frac{V_{os}}{(dv)(\text{sample rate})} \quad (3)$$

$$= 150 \text{ msec}$$

If this is too slow, the step size can be increased.

OP AMP INPUT BIAS CURRENT

Input bias current should be considered when selecting an op amp that is nulled by the LMC669. If this current is too high, the result is a significant voltage drop across the feedback components and consequent output offset. The Auto Zero will not correct this error since it does not appear as a voltage at the summing node. Therefore, use low resistance feedback networks, or op amps with low input bias current such as the LF156, LF400, and LF411.

NOISE

Through careful selection of the sample rate and step size a compromise can be made between noise and null time. Low sample rates achieve low noise but take a long time to null an offset or correct it when a sudden change occurs. High sample rates can quickly null or correct changes in V_{os} but do so with an increase in noise. Step size directly affects the null time and the amount of noise introduced: small step sizes ($< 100 nV$) contribute almost no noise, but result in long null times.

Low noise LMC669 applications are beneficial to instrumentation and audio electronics. An LM833 low noise operational amplifier ($4.5 nV / \sqrt{Hz}$) with the LMC669 is shown in *Figure 4*. In this circuit the Auto Zero adds only $1 nV / \sqrt{Hz}$ referred to the amplifier's input. To achieve this the step size is set to $100 nV$. The sample rate, with the internal clock free-running, is set to $98 Hz$ (clock frequency $\div 1024$), and input and output filters are added to the LMC669. The input filter prevents switching transients from reaching the amplifier input and the output filter attenuates AC components of the steps at the Auto Zero's output. The filter at the op amp's input also introduces a pole at

$$F_p = \frac{1}{2\pi(R_{in} + R_i)C_i}$$

and a zero at

$$F_z = \frac{1}{2\pi R_i C_i}$$

The maximum V_{os} that can be corrected by the circuit in *Figure 4* is $12 mV$. More offset correction can be obtained while retaining good noise performance by increasing the size of R_2 and C the same percentage. Increasing C compensates for the reduced attenuation caused by increasing R_2 . This allows the step size to remain the same but increases the amount of correction voltage applied to the op amp.

FIGURE 5. Zeroing LM1875 Power Op-Amp

TL/H/8561-10

Application Hints (Continued)

POWER AMPLIFIERS

For applications such as motor control, automated servo systems, and power amplification the LMC669 can also be used with amplifiers other than standard small signal op amps. *Figure 5* shows how the Auto Zero can allow an LM1875 audio power amplifier to operate with very low offset. While the sample rate for this configuration is not critical, the LMC669's output step size should be set for less than $1\ \mu\text{V}$ to ensure low system noise.

NON-INVERTING AMPLIFIERS AND SYSTEMS

A variation of the above circuit appears in *Figure 6* with the LMC669 operating as a DC-servo integrating feedback loop. This configuration is applicable when the Auto Zero is used with non-inverting op amps amplifying AC-only signals. The output error of the amplifier is reduced to the V_{OS} of the Auto Zero, typically $5\ \mu\text{V}$. A filter at the input of the LMC669 limits current and ensures that only DC and very low frequencies

(< 0.6 Hz) are sampled. In this application the output of the op amp is sampled and compared with a reference ground. The correction output from the Auto Zero now replaces the ground reference for the feedback resistor connected to the inverting input.

Systems can also benefit from the Auto Zero. *Figure 7* shows how the V_{OS} of an MF6 Butterworth low-pass switched capacitor filter is nulled by the LMC669. The Auto Zero's IN1 and IN2 inputs are connected to the MF6's output while INREF is connected to its input. The correction signal is applied to the MF6's V_{OS} ADJ input. RC low-pass filters (R_{f1} , C_{f1} and R_{f2} , C_{f2}) are used to reduce AC signals at the LMC669's inputs and provide current limiting. It is important to set each passive RC filter's cutoff as low as possible, at most 0.1 of the MF6's f_o .

This correction makes the MF6 useful in applications calling for good DC accuracy. The MF6's typical 250 mV offset is decreased to $5\ \mu\text{V}$ with a step size of $1\ \mu\text{V}$.

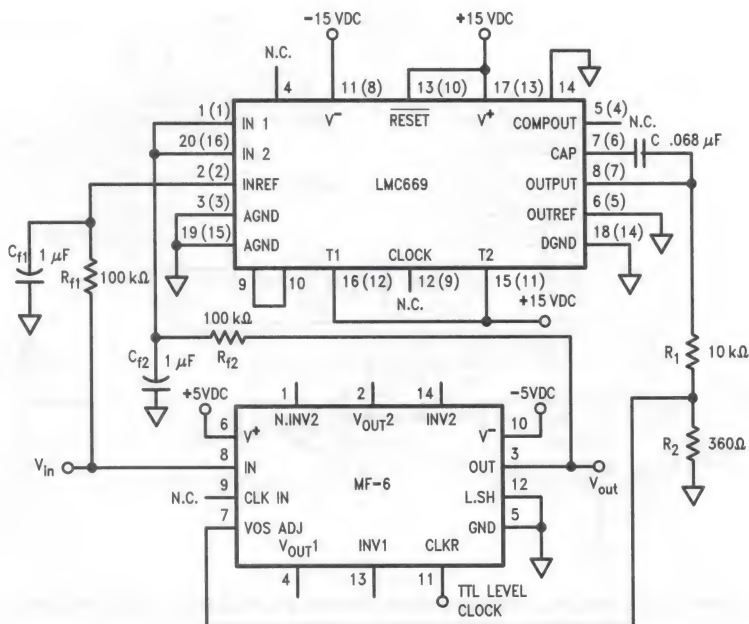

FIGURE 6. DC Servo Loop

Application Hints (Continued)

TL/H/8561-12

FIGURE 7. Auto zeroing a system. In this case the 250 mV offset of a switched-capacitor low-pass filter is corrected by the LMC669.

MAINTAINING DAC LINEARITY

The LMC669 is particularly useful for zeroing the offset of an op amp used with a CMOS digital-to-analog converter (DAC). For good linearity the DAC's two outputs (I_{OUT} and $\overline{I_{OUT}}$) must be connected to identical ground potentials. The presence of op amp V_{OS} (and its drift due to temperature) will degrade the DAC's linearity. Even though the effects of V_{OS} can be corrected by trimming, a static trim will not be very helpful if the V_{OS} changes with respect to temperature.

Figure 8 shows the DAC1208 with a 10V reference driving an LF357. The linearity of this DAC will degrade by 0.01% for each millivolt of op amp V_{OS} . Therefore, the LF357's typical offset of 5 mV will turn the 12-bit DAC1208's 0.012% linearity error into 0.062%. What was a 12 bit linear device now has only 9 bits linearity. The original linearity specification can be retained by connecting an LMC669 to the inputs of the LF357, rendering the non-linearity due to V_{OS} and temperature drift negligible. The DAC is now able to operate at its published linearity specifications independent of V_{OS} and temperature.

Figure 9 shows the schematic of a unipolar power DAC. One use of the power DAC is as a digitally controlled power supply having the ability to sink current, in the case of inductive loads, as well as source current. The linearity of the DAC is preserved by the nulling action of the LMC669 connected to the inputs of the LM1875 power amplifier. The

amplifier can generate an output voltage from 0 to 25 volts and a maximum current of 3 amperes. The actual output is determined by

$$V_{out} = \frac{-V_{ref}(D)}{4096}$$

("D" is the value of the digital code, base 10). The magnitude of each step is

$$1 \text{ LSB} = \frac{|V_{ref}|}{4096}$$

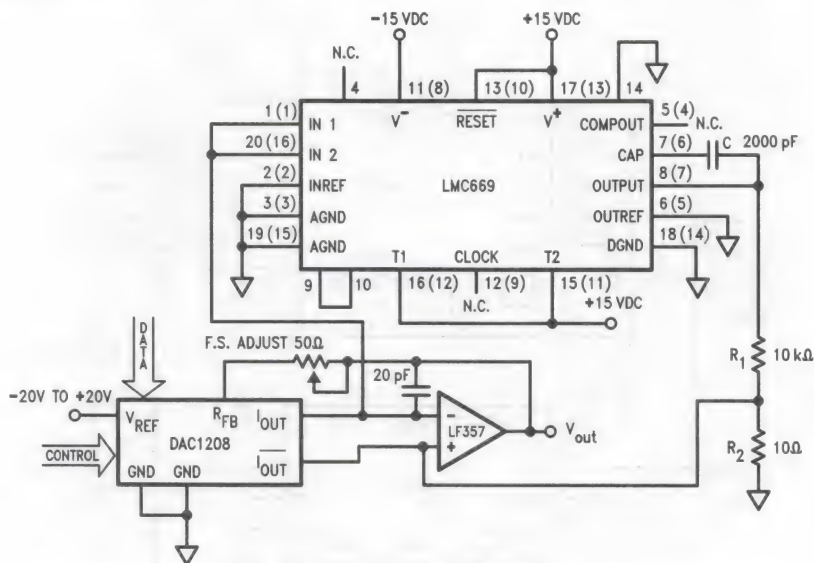

Stable operation of the LM1875 is ensured by the RC combination connected to the inverting input.

LMC669 AS A COMPARATOR

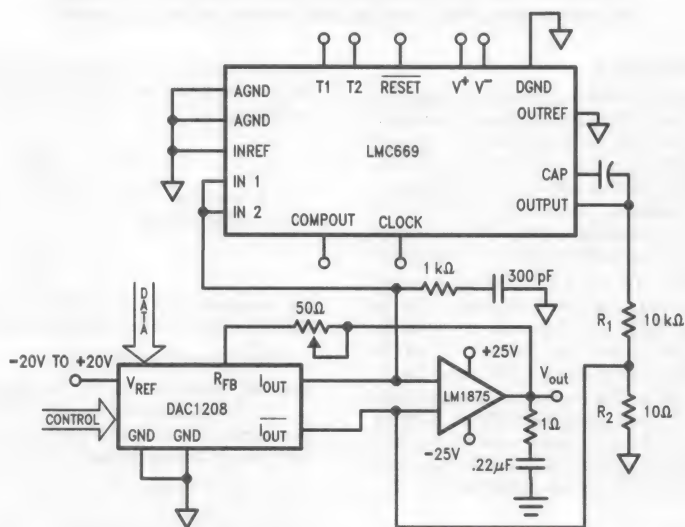

The LMC669's operation as a comparator is shown in Figure 10. Its input impedance is 5 kΩ with 160 pF to ground. For proper operation as a comparator IN1 and IN2, or INREF, should be kept between 0 and 2V while the other input (or inputs) can be taken to V^+ . If input current limiting (≤ 20 mA) is provided, the inputs can also go to V^- . (In addition, please refer to notes 3 and 5 under "Electrical Characteristics".)

The open collector output can be pulled-up to typically 25 volts. When the sink current is 1 mA the output can pull-down to 0.25V. Outputs closer to ground are possible with a larger pullup resistor.

LOW-FREQUENCY, HIGH-GAIN AMPLIFIER

For applications that require precision high-gain DC and low-frequency performance, the LMC669 can be connected as an amplifier as shown in Figure 11. For a closed-loop gain of -1000 the useful frequency range is typically

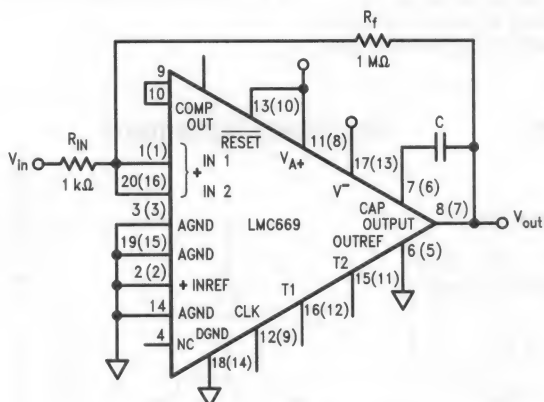

$$F_{\max} = 20 \frac{\text{Hz}}{\text{mV of step size}}$$

PRELIMINARY

LP124/LP2902/LP324 Micropower Quad Operational Amplifier

General Description

The LP124 series consists of four independent, high gain internally compensated micropower operational amplifiers. These amplifiers are specially suited for operation in battery systems while maintaining good input specifications, and extremely low supply current drain. In addition, the LP124 has an input common mode range, and output source range which includes ground, making it ideal in single supply applications.

These amplifiers are ideal in applications which include portable instrumentation, battery backup equipment, and other circuits which require good DC performance and low supply current.

Features

- Low supply current 125 μ A (max)
- Low offset voltage 2 mV (max)
- Low input bias current 4 nA (max)
- Input common mode to GND
- Interfaces to CMOS logic
- Wide supply range $3V < V^+ < 32V$
- Small Outline Package available
- Pin-for-pin compatible with LM124

GBW	Gain Bandwidth Product		100			100			100			KHz
S_r	Slew Rate		50			50			50			V/mS

Note 1: The input voltage is not allowed to go more than -0.3V below V^- (GND) as this will turn on a parasitic transistor causing large currents to flow through the device.

Note 2: Short circuits from the output to GND can cause excessive heating and eventual destruction. The maximum sourcing output current is approximately 30 mA independent of the magnitude of V^+ . At values of supply voltage in excess of 15V_{DC} , continuous short-circuit to GND can exceed the power dissipation ratings (particularly at elevated temperatures) and cause eventual destruction. Destructive dissipation can result from simultaneous shorts on all amplifiers.

Note 3: For operation at elevated temperatures, these devices must be derated based on a thermal resistance of θ_{JA} and $T_{\text{J max}}$. $T_{\text{J}} = T_{\text{A}} + \theta_{\text{JA}}P_{\text{D}}$.

Note 4: The LP124 may be operated from $-55^\circ\text{C} \leq T_{\text{A}} \leq +125^\circ\text{C}$. The LP2902 may be operated from $-40^\circ\text{C} \leq T_{\text{A}} \leq +85^\circ\text{C}$, and the LP324 may be operated from $0^\circ\text{C} \leq T_{\text{A}} \leq +70^\circ\text{C}$.

Note 5: Boldface numbers apply at temperature extremes. All other numbers apply only at $T_{\text{A}} = T_{\text{J}} = 25^\circ\text{C}$, $V^+ = 5\text{V}$, $V_{\text{cm}} = V/2$, and $R_{\text{L}} = 100\text{k}\Omega$ connected to GND unless otherwise specified.

Note 6: Guaranteed and 100% production tested.

Note 7: Guaranteed (but not 100% production tested) over the operating supply voltage range (3.0V to 32V for the LP124, LP324, and 3.0V to 26V for the LP2902), and the common mode range (0V to $V^+ - 1.5\text{V}$), unless otherwise specified. These limits are not used to calculate outgoing quality levels.

Note 8: The LP2902 operating supply range is 3V to 26V, and is not tested above 26V.

Note 9: The test circuit used consists of the human body model of 100 pF in series with 1500 Ω .

Typical Performance Curves (Continued)

TL/H/8562-20

TL/H/8562-19

Application Hints

The LP124 series is a micro-power pin-for-pin equivalent to the LM124 op amps. Power supply current, input bias current, and input offset current have all been reduced by a factor of 10 over the LM124. Like its predecessor, the LP124 series op amps can operate on single supply, have true-differential inputs, and remain in the linear mode with an input common-mode voltage of 0 V_{DC} .

The pinouts of the package have been designed to simplify PC board layouts. Inverting inputs are adjacent to outputs for all of the amplifiers and the outputs have also been placed at the corners of the package (pins 1, 7, 8, and 14).

Precautions should be taken to insure that the power supply for the integrated circuit never becomes reversed in polarity or the unit is not inadvertently installed backwards in the

test socket as an unlimited current surge through the resulting forward diode within the IC could destroy the unit.

Large differential input voltages can be easily accommodated and, as input differential voltage protection diodes are not needed, no large input currents result from large differential input voltages. The differential input voltage may be larger than V^+ without damaging the device. Protection should be provided to prevent the input voltages from going negative more than $-0.3 V_{DC}$ (at $25^\circ C$). An input clamp diode with a resistor to the IC input terminal can be used.

The amplifiers have a class B output stage which allows the amplifiers to both source and sink output currents. In applications where crossover distortion is undesirable, a resistor

Application Hints (Continued)

should be used from the output of the amplifier to ground. The resistor biases the output into class A operation.

The LP124 has improved stability margin for driving capacitive loads. No special precautions are needed to drive loads in the 50 pF to 1000 pF range. It should be noted however that since the power supply current has been reduced by a factor of 10, so also has the slew rate and gain bandwidth product. This reduction can cause reduced performance in AC applications where the LM124 is being replaced by an LP124. Such situations usually occur when the LM124 has been operated near its power bandwidth.

Output short circuits either to ground or to the positive power supply should be of short time duration. Units can be destroyed, not as a result of the short circuit current causing metal fusing, but rather due to the large increase in IC chip dissipation which will cause eventual failure due to excessive junction temperatures. For example: If all four amplifiers were simultaneously shorted to ground on a 10V supply the junction temperature would rise by 110°C.

Exceeding the negative common-mode limit on either input will cause a reversal of phase to the output and force

the amplifier to the corresponding high or low state. Exceeding the negative common-mode limit on both inputs will force the amplifier output to a high state. Exceeding the positive common-mode limit on a single input will not change the phase of the output. However, if both inputs exceed the limit, the output of the amplifier will be forced to a low state. In neither case does a latch occur since returning the input within the common mode range puts the input stage and thus the amplifier in a normal operating mode.

The circuits presented in the section on typical applications emphasize operation on only a single power supply voltage. If complementary power supplies are available, all of the standard op amp circuits can be used. In general, introducing a pseudo-ground (a bias voltage reference to $V^+ / 2$) will allow operation above and below this value in single power supply systems. Many application circuits are shown which take advantage of the wide input common-mode voltage range which includes ground. In most cases, input biasing is not required and input voltages which range to ground can easily be accommodated.

TL081CP Wide Bandwidth JFET Input Operational Amplifier

General Description

The TL081 is a low cost high speed JFET input operational amplifier with an internally trimmed input offset voltage (BI-FET II™ technology). The device requires a low supply current and yet maintains a large gain bandwidth product and a fast slew rate. In addition, well matched high voltage JFET input devices provide very low input bias and offset currents. The TL081 is pin compatible with the standard LM741 and uses the same offset voltage adjustment circuitry. This feature allows designers to immediately upgrade the overall performance of existing LM741 designs.

The TL081 may be used in applications such as high speed integrators, fast D/A converters, sample-and-hold circuits and many other circuits requiring low input offset voltage, low input bias current, high input impedance, high slew rate and wide bandwidth. The devices has low noise and offset voltage drift, but for applications where these requirements

are critical, the LF356 is recommended. If maximum supply current is important, however, the TL081C is the better choice.

Features

- Internally trimmed offset voltage 15 mV
- Low input bias current 50 pA
- Low input noise voltage 25 nV/√Hz
- Low input noise current 0.01 pA/√Hz
- Wide gain bandwidth 4 MHz
- High slew rate 13 V/μs
- Low supply current 1.8 mA
- High input impedance 10¹²Ω
- Low total harmonic distortion $A_V = 10$, $R_L = 10k$, $V_O = 20$ Vp-p, BW = 20 Hz–20 kHz <0.02%
- Low 1/f noise corner 50 Hz
- Fast settling time to 0.01% 2 μs

AC Electrical Characteristics (Note 3)

Symbol	Parameter	Conditions	TL081C			Units
			Min	Typ	Max	
SR	Slew Rate	V _S = ±15V, T _A = 25°C		13		V/μs
GBW	Gain Bandwidth Product	V _S = ±15V, T _A = 25°C		4		MHz
e _n	Equivalent Input Noise Voltage	T _A = 25°C, R _S = 100Ω, f = 1000 Hz		25		nV/√Hz
i _n	Equivalent Input Noise Current	T _j = 25°C, f = 1000 Hz		0.01		pA/√Hz

Note 1: For operating at elevated temperature, the device must be derated based on a thermal resistance of 120°C/W junction to ambient for N package.

Note 2: Unless otherwise specified the absolute maximum negative input voltage is equal to the negative power supply voltage.

Note 3: These specifications apply for V_S = ±15V and 0°C ≤ T_A ≤ +70°C. V_{OS}, I_B and I_{OS} are measured at V_{CM} = 0.

Note 4: The input bias currents are junction leakage currents which approximately double for every 10°C increase in the junction temperature, T_j. Due to the limited production test time, the input bias currents measured are correlated to junction temperature. In normal operation the junction temperature rises above the ambient temperature as a result of internal power dissipation, P_D. T_j = T_A + θ_{JA} P_D where θ_{JA} is the thermal resistance from junction to ambient. Use of a heat sink is recommended if input bias current is to be kept to a minimum.

Note 5: Supply voltage rejection ratio is measured for both supply magnitudes increasing or decreasing simultaneously in accordance with common practice from V_S = ±5V to ±15V.

Note 6: Max. Power Dissipation is defined by the package characteristics. Operating the part near the Max. Power Dissipation may cause the part to operate outside guaranteed limits.

Application Hints

The TL081 is an op amp with an internally trimmed input offset voltage and JFET input devices (BI-FET II). These JFETs have large reverse breakdown voltages from gate to source and drain eliminating the need for clamps across the inputs. Therefore, large differential input voltages can easily be accommodated without a large increase in input current. The maximum differential input voltage is independent of the supply voltages. However, neither of the input voltages should be allowed to exceed the negative supply as this

will cause large currents to flow which can result in a destroyed unit.

Exceeding the negative common-mode limit on either input will force the output to a high state, potentially causing a reversal of phase to the output.

Exceeding the negative common-mode limit on both inputs will force the amplifier output to a high state. In neither case does a latch occur since raising the input back within the

Application Hints (Continued)

common-mode range again puts the input stage and thus the amplifier in a normal operating mode.

Exceeding the positive common-mode limit on a single input will not change the phase of the output; however, if both inputs exceed the limit, the output of the amplifier will be forced to a high state.

The amplifier will operate with a common-mode input voltage equal to the positive supply; however, the gain bandwidth and slew rate may be decreased in this condition. When the negative common-mode voltage swings to within 3V of the negative supply, an increase in input offset voltage may occur.

The TL081 is biased by a zener reference which allows normal circuit operation on $\pm 4\text{V}$ power supplies. Supply voltages less than these may result in lower gain bandwidth and slew rate.

The TL081 will drive a $2\text{ k}\Omega$ load resistance to $\pm 10\text{V}$ over the full temperature range of 0°C to $+70^\circ\text{C}$. If the amplifier is forced to drive heavier load currents, however, an increase in input offset voltage may occur on the negative voltage swing and finally reach an active current limit on both positive and negative swings.

Precautions should be taken to ensure that the power supply for the integrated circuit never becomes reversed in polarity or that the unit is not inadvertently installed backwards in a socket as an unlimited current surge through the

resulting forward diode within the IC could cause fusing of the internal conductors and result in a destroyed unit.

Because these amplifiers are JFET rather than MOSFET input op amps they do not require special handling.

As with most amplifiers, care should be taken with lead dress, component placement and supply decoupling in order to ensure stability. For example, resistors from the output to an input should be placed with the body close to the input to minimize "pick-up" and maximize the frequency of the feedback pole by minimizing the capacitance from the input to ground.

A feedback pole is created when the feedback around any amplifier is resistive. The parallel resistance and capacitance from the input of the device (usually the inverting input) to AC ground set the frequency of the pole. In many instances the frequency of this pole is much greater than the expected 3 dB frequency of the closed loop gain and consequently there is negligible effect on stability margin. However, if the feedback pole is less than approximately 6 times the expected 3 dB frequency a lead capacitor should be placed from the output to the input of the op amp. The value of the added capacitor should be such that the RC time constant of this capacitor and the resistance it parallels is greater than or equal to the original feedback pole time constant.

PRELIMINARY

TL082CP Wide Bandwidth Dual JFET Input Operational Amplifier

General Description

These devices are low cost, high speed, dual JFET input operational amplifiers with an internally trimmed input offset voltage (BI-FET II™ technology). They require low supply current yet maintain a large gain bandwidth product and fast slew rate. In addition, well matched high voltage JFET input devices provide very low input bias and offset currents. The TL082 is pin compatible with the standard LM1558 allowing designers to immediately upgrade the overall performance of existing LM1558 and most LM358 designs.

These amplifiers may be used in applications such as high speed integrators, fast D/A converters, sample and hold circuits and many other circuits requiring low input offset voltage, low input bias current, high input impedance, high slew rate and wide bandwidth. The devices also exhibit low noise and offset voltage drift.

Features

- Internally trimmed offset voltage 15 mV
- Low input bias current 50 pA
- Low input noise voltage 16 nV/√Hz
- Low input noise current 0.01 pA/√Hz
- Wide gain bandwidth 4 MHz
- High slew rate 13 V/μs
- Low supply current 3.6 mA
- High input impedance 10¹² Ω
- Low total harmonic distortion $A_V = 10$, $R_L = 10k$, $V_O = 20 V_p - p$, $BW = 20 \text{ Hz} - 20 \text{ kHz}$ <0.02%
- Low 1/f noise corner 50 Hz
- Fast settling time to 0.01% 2 μs

Buffers

Definition of Terms

Bandwidth: That frequency at which the voltage gain is reduced to $1/\sqrt{2}$ times the low frequency value.

Common-Mode Rejection Ratio: The ratio of the input common-mode voltage range to the peak-to-peak change in input offset voltage over this range.

Harmonic Distortion: That percentage of harmonic distortion being defined as one-hundred times the ratio of the root-mean-square (rms) sum of the harmonics to the fundamental.

$$\% \text{ harmonic distortion} = \frac{(V_2^2 + V_3^2 + V_4^2 + \dots)^{1/2} (100\%)}{V_1}$$

where V_1 is the rms amplitude of the fundamental and V_2 , V_3 , V_4 , . . . are the rms amplitudes of the individual harmonics.

Input Bias Current: The average of the two input currents.

Input Common-Mode Voltage Range: The range of voltages on the input terminals for which the amplifier is operational. Note that the specifications are not guaranteed over the full common-mode voltage range unless specifically stated.

Input Impedance: The ratio of input voltage to input current under the stated conditions for source resistance (R_S) and load resistance (R_L).

Input Offset Current: The difference in the currents into the two input terminals when the output is at zero.

Input Offset Voltage: That voltage which must be applied between the input terminals through two equal resistances to obtain zero output voltage.

Input Resistance: The ratio of the change in input voltage to the change in input current on either input with the other grounded.

Input Voltage Range: The range of voltages on the input terminals for which the amplifier operates within specifications.

Large-Signal Voltage Gain: The ratio of the output voltage swing to the change in input voltage required to drive the output from zero to this voltage.

Output Impedance: The ratio of output voltage to output current under the stated conditions for source resistance (R_S) and load resistance (R_L).

Output Resistance: The small signal resistance seen at the output with the output voltage near zero.

Output Voltage Swing: The peak output voltage swing, referred to zero, that can be obtained without clipping.

Offset Voltage Temperature Drift: The average drift rate of offset voltage for a thermal variation from room temperature to the indicated temperature extreme.

Power Supply Rejection: The ratio of the change in input offset voltage to the change in power supply voltages producing it.

Settling Time: The time between the initiation of the input step function and the time when the output voltage has settled to within a specified error band of the final output voltage.

Slew Rate: The internally-limited rate of change in output voltage with a large-amplitude step function applied to the input.

Supply Current: The current required from the power supply to operate the amplifier with no load and the output midway between the supplies.

Transient Response: The closed-loop step-function response of the amplifier under small-signal conditions.

Unity Gain Bandwidth: The frequency range from dc to the frequency where the amplifier open loop gain rolls off to one.

Voltage Gain: The ratio of output voltage to input voltage under the stated conditions for source resistance (R_S) and load resistance (R_L).

LH0002/LH0002C Current Amplifier

General Description

The LH0002/LH0002C is a general purpose current amplifier.

Features

- High input impedance 400 k Ω
- Low output impedance 6 Ω
- High power efficiency
- Low harmonic distortion
- DC to 30 MHz bandwidth
- Output voltage swing that approaches supply voltage
- 400 mA pulsed output current
- Slew rate is typically 200 V/ μ s
- Operation from ± 5 V to ± 20 V

These features make it ideal to integrate with an operational amplifier inside a closed loop configuration to increase current output. The symmetrical output portion of the cir-

cuit also provides a low output impedance for both the positive and negative slopes of output pulses.

The LH0002 is available in an 8-lead low-profile TO-5 header and a 20-pin leadless chip carrier; the LH0002C is also available in an 8-lead TO-5, and a 10-pin molded dual-in-line package.

The LH0002 is specified for operation over the -55°C to $+125^{\circ}\text{C}$ military temperature range. The LH0002C is specified for operation over the 0°C to $+85^{\circ}\text{C}$ temperature range.

Applications

- Line driver
- 30 MHz buffer
- High speed D/A conversion
- Instrumentation buffer
- Precision current source

LH0033/LH0033A/LH0033C/LH0033AC/LH0063/ LH0063C Fast and Ultra Fast Buffer Amplifiers

General Description

The LH0033/LH0033A and LH0063 are high speed, FET input, voltage follower/buffers designed to provide high current drive at frequencies from DC to over 100 MHz. The LH0033/LH0033A will provide ± 10 mA into 1 k Ω loads (± 100 mA peak) at slew rates of 1500V/ μ s. The LH0063 will provide ± 250 mA into 50 Ω loads (± 500 mA peak) at slew rates up to 6000V/ μ s. In addition, both exhibit excellent phase linearity up to 20 MHz.

Both are intended to fulfill a wide range of buffer applications such as high speed line drivers, video impedance transformation, nuclear instrumentation amplifiers, op amp isolation buffers for driving reactive loads and high impedance input buffers for high speed A to Ds and comparators. In addition, the LH0063 can continuously drive 50 Ω coaxial cables or be used as a yoke driver for high resolution CRT displays. For additional applications information, see AN-48.

These devices are constructed using specially selected junction FETs and active laser trimming to achieve guaranteed performance specifications. The LH0033/LH0033A and LH0063 are specified for operation from -55°C to $+125^{\circ}\text{C}$; whereas, the LH0033C/LH0033AC and LH0063C are specified from -25°C to $+85^{\circ}\text{C}$. The LH0033/

LH0033A is available in either a 1.5W metal TO-8 package or an 8-pin ceramic dual-in-line package. The LH0063 is available in a 5W 8-pin TO-3 package.

Features

- Ultra fast (LH0063): 6000 V/ μ s
- Wide range single or dual supply operation
- Wide power bandwidth: DC to 100 MHz
- High output drive: ± 10 V with 50 Ω load
- Low phase non-linearity: 2 degrees
- Fast rise times: 2 ns
- High current gain: 120 dB
- High input resistance: $10^{10}\Omega$

Advantages

- Only 10V supply needed for 5 Vp-p video out
- Speed does not degrade system performance
- Wide data rate range for phase encoded systems
- Output drive adequate for most loads
- Single pre-calibrated package

Note 1: LH0033 and LH0033A are 100% production tested as specified at 25°C, 125°C, and -55°C. LH0033AC/C are 100% production tested at 25°C only. Specifications at temperature extremes are verified by sample testing, but these limited are not used to calculate outgoing quality level.

Note 2: Specification is at 25°C junction temperature due to requirements of high speed automatic testing. Actual values at operating temperature will exceed the value at $T_J = 25^\circ\text{C}$. When supply voltages are $\pm 15V$, no-load operating junction temperature may rise 40-60°C above ambient, and more under load conditions. Accordingly, V_{OS} may change one to several mV, and I_B will change significantly during warm-up. Refer to I_B vs temperature graph for expected values.

Note 3: LH0033 and LH0033A are 100% production tested for this parameter. LH0033AC/C are sample tested only. Limits are not used to calculate outgoing quality levels. $\Delta V_{OS}/\Delta T$ is the average value calculated from measurements at 25°C and T_{MAX} .

Note 4: Measured in still air 7 minutes after application of power. Guaranteed through correlated automatic pulse testing.

Note 5: Guaranteed through correlated automatic pulse testing at $T_J = 25^\circ\text{C}$.

Note 6: Not 100% production tested; verified by sample testing only. Limits are not used to calculate outgoing quality level.

Note 7: Refer to RETS0033AG for the LH0033AG and RETS0033G for the LH0033G military specifications.

DC Electrical Characteristics $V_S = \pm 15V$, $T_{MIN} \leq T_A \leq T_{MAX}$ unless otherwise specified (Note 1)

Application Hints

RECOMMENDED LAYOUT PRECAUTIONS

RF/video printed circuit board layout rules should be followed when using the LH0033 and LH0063 since they will provide power gain to frequencies over 100 MHz. Ground planes are recommended and power supplies should be decoupled at each device with low inductance capacitors. In addition, ground plane shielding may be extended to the metal case of the device since it is electrically isolated from internal circuitry. Alternatively the case should be connected to the output to minimize input capacitance.

OFFSET VOLTAGE ADJUSTMENT

Both the LH0033's and LH0063's offset voltages have been actively trimmed by laser to meet guaranteed specifications when the offset preset pin is shorted to the offset adjust pin. This pre-calibration allows the devices to be used in most DC or AC applications without individually offset nulling each device. If offset null is desirable, it is simply obtained by leaving the offset preset pin open and connecting a trim pot of 100Ω for the LH0033 or 1 kΩ for the LH0063 between the offset adjust pin and V^- , as illustrated in Figures 1 and 2.

TL/K/5507-6

FIGURE 1. Offset Zero Adjust for LH0033
(Pin numbers shown for TO-8)

TL/K/5507-7

FIGURE 2. Offset Zero Adjust for LH0063

Application Hints (Continued)

OPERATION FROM SINGLE OR ASYMMETRICAL POWER SUPPLIES

Both device types may be readily used in applications where symmetrical supplies are unavailable or not desirable. A typical application might be an interface to a MOS shift register where $V^+ = +5V$ and $V^- = -12V$. In this case, an apparent output offset occurs due to the device's voltage gain of less than unity. This additional output offset error may be predicted by:

$$\Delta V_O \approx (1 - A_V) \frac{(V^+ - V^-)}{2} = 0.005(V^+ - V^-)$$

where:

A_V = No load voltage gain, typically 0.99

V^+ = Positive supply voltage

V^- = Negative supply voltage

For the above example, ΔV_O would be $-35mV$. This may be adjusted to zero as described in *Figure 2*. For AC coupled applications, no additional offset occurs if the DC input is properly biased as illustrated in the Typical Applications section.

SHORT CIRCUIT PROTECTION

In order to optimize transient response and output swing, output current limit has been omitted from the LH0033 and LH0063. Short circuit protection may be added by inserting appropriate value resistors between V^+ and V_C^+ pins and V^- and V_C^- pins as illustrated in *Figures 3 and 4*. Resistor values may be predicted by:

$$R_{LIM} \approx \frac{V^+}{I_{SC}} = \frac{V^-}{I_{SC}}$$

where:

$I_{SC} \leq 100 \text{ mA}$ for LH0033

$I_{SC} \leq 250 \text{ mA}$ for LH0063

TL/K/5507-8

FIGURE 3. LH0033 Using Resistor Current Limiting

TL/K/5507-9

FIGURE 4. LH0063 Using Resistor Current Limiting

Application Hints (Continued)

The inclusion of limiting resistors in the collectors of the output transistors reduces output voltage swing. Decoupling V_C^+ and V_C^- pins with capacitors to ground will retain full output swing for transient pulses. Alternate active current limit techniques that retain full DC output swing are shown in Figures 5 and 6. In Figures 5 and 6, the current sources are saturated during normal operation, thus apply full supply voltage to the V_C pins. Under fault conditions, the voltage decreases as required by the overload.

For Figure 5:

$$R_{LIM} = \frac{V_{BE}}{I_{SC}} = \frac{0.6V}{60mA} = 10\Omega$$

In Figure 6, quad transistor arrays are used to minimize can count and:

$$R_{LIM} = \frac{V_{BE}}{1/3(I_{SC})} = \frac{0.6V}{1/3(200mA)} = 8.2\Omega$$

FIGURE 5. LH0033 Current Limiting Using Current Sources

FIGURE 6. LH0063 Current Limiting Using Current Sources

CAPACITIVE LOADING

Both the LH0033 and LH0063 are designed to drive capacitive loads such as coaxial cables in excess of several thousand picofarads without susceptibility to oscillation. However, peak current resulting from $(C \times dv/dt)$ should be limited below absolute maximum peak current ratings for the devices.

Thus for the LH0033:

$$\left(\frac{\Delta V_{IN}}{\Delta t} \right) \times C_L \leq I_{OUT} \leq \pm 250mA$$

and for the LH0063:

$$\left(\frac{\Delta V_{IN}}{\Delta t} \right) \times C_L \leq I_{OUT} \leq \pm 500mA$$

In addition, power dissipation resulting from driving capacitive loads plus standby power should be kept below total package power rating:

$$P_{Dpkg} \geq P_{DC} + P_{AC}$$

$$P_{Dpkg} \geq (V^+ - V^-) \times I_S + P_{AC}$$

$$P_{AC} \approx (V_p - p)^2 \times f \times C_L$$

where:

$V_p - p$ = Peak-to-peak output voltage swing

f = Frequency

C_L = Load Capacitance

OPERATION WITHIN AN OP AMP LOOP

Both devices may be used as a current booster or isolation buffer within a closed loop with op amps such as LH0032, LH0062, or LM118. An isolation resistor of 47Ω should be used between the op amp output and the input of LH0033. The wide bandwidths and high slew rates of the LH0033 and LH0063 assure that the loop has the characteristics of the op amp and that additional rolloff is not required.

HARDWARE

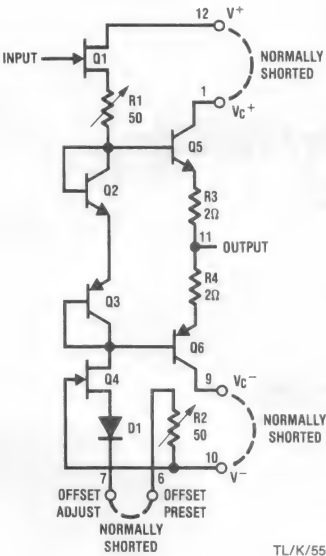

In order to utilize the full drive capabilities of both devices, each should be mounted with a heat sink particularly for extended temperature operation. The cases of both are isolated from the circuit and may be connected to the system chassis.

DESIGN PRECAUTION

Power supply bypassing is necessary to prevent oscillation with both the LH0033 and LH0063 in all circuits. Low inductance ceramic disc capacitors with the shortest practical lead lengths must be connected from each supply lead (within $<1/4$ to $1/2$ " of the device package) to a ground plane. Capacitors should be one or two $0.1 \mu F$ in parallel for the LH0033; adding a $4.7 \mu F$ solid tantalum capacitor will help in troublesome instances. For the LH0063, two $0.1 \mu F$ ceramic and one $4.7 \mu F$ solid tantalum capacitors in parallel will be necessary on each supply lead.

LH4001 Wideband Current Buffer

General Description

The LH4001 is a high speed unity gain buffer designed to provide high current drive capability at frequencies from DC to over 25 MHz. It is capable of providing a continuous output current of ± 100 mA and a peak of ± 200 mA.

The LH4001 is designed to fulfill a wide range of applications such as impedance transformation, high impedance input buffers for A/D converters and comparators, as well as high speed line drivers. It is also suitable for use in current booster applications within an op amp loop. This allows the output current capability of existing op amps to be increased to ± 100 mA.

Features

- DC to 25 MHz bandwidth
- 125 V/ μ s slew rate
- Drives ± 10 V into 50 Ω
- Operates from ± 5 to ± 20 V supplies
- Output swing approaches supply voltage

Applications

- Boost op amp output
- Buffer amplifiers
- Isolate capacitive loads
- Drive long cables

Applications Information

Figure 1 shows a simple implementation of a non-inverting buffer amplifier of unity gain. Popular industry standard operational amplifiers such as LF156, LF351, LF411, LF441, LM11, LM741, etc. can be used in this configuration. Due to the high bandwidth of the LH4001, it is suitable for use with most monolithic op amps.

Figure 2 shows an implementation of an inverting amplifier with output current capability in excess of ± 100 mA. The gain of this amplifier is determined by the values of R_F and R_{IN} . The resistor between the non-inverting input and ground is used to minimize the output offset voltage resulting from the input bias current.

Because of its high current drive capability, the LH4001 buffer amplifier is suitable for driving terminated or unterminated co-axial cables, and high current or reactive loads.

Figure 3 shows a co-axial cable drive circuit. The 43Ω resistor matches the driving source to the cable, however, its inclusion rarely will result in substantial improvement in pulse response into a terminated cable. If the 43Ω resistor is included, the output voltage to the load is about half what it would be without the near end termination.

Figure 4 shows a non-inverting amplifier with gain and output current capability in excess of ± 100 mA. It is capable of providing ± 10 mA into a $1\text{ k}\Omega$ load or ± 100 mA into a 100Ω load ($\pm 10\text{V}$ swing). Figures 5 and 6 show two different methods of providing current limit or short circuit protection for the LH4001. In Figure 6, the 10Ω resistor limits the output current to approximately 70 mA. This circuit is highly recommended if there is a potential for a short circuit to occur.

LH4002 Wideband Video Buffer

General Description

The LH4002 is a high speed voltage follower designed to drive video signals from DC up to 200 MHz. At voltage supplies of $\pm 5V$, the LH4002 will provide up to 40 mA into 50Ω at slew rates in excess of $1000 V/\mu s$.

The device is intended to fulfill a wide range of high speed applications including video distribution, impedance transformation, and load isolation. It is also suitable for use in current booster applications within an op amp loop. This allows the output current capability of existing op amps to be increased.

Features

- DC to 200 MHz Bandwidth with $V_S = \pm 5V$
- $1250 V/\mu s$ Slew Rate into 50Ω
- 150 MHz Bandwidth with $V_S = \pm 5V$, $R_L = 50\Omega$ and Voltage Swing = $2 V_{P-P}$

Applications

- Wideband Buffer Amplifiers
- Wideband Line Driver

FIGURE 2. Compensation for Capacitive Loads

TL/K/8686-10

FIGURE 3. Compensation for Capacitive Loads

Applications Information

The high speed performance of the LH4002 can only be realized by taking certain precautions in circuit layout and power supply decoupling. Low inductance ceramic chip or disc power supply decoupling capacitors of $0.01 \mu\text{F}$ in parallel with $0.1 \mu\text{F}$ should be connected with the shortest practical lead length between device supply leads and a ground plane. Failure to follow these rules can result in oscillations.

When driving a capacitive load such as inputs to flash converters, the circuits in *Figure 2* and *3* can be used to minimize the amount of overshoot and ringing at the outputs. *Figure 2* indicates that a 50Ω should be placed in parallel with the load and *Figure 3* recommends that a 100Ω resistor be placed in series with the input to the LH4002.

TL/K/8686-14

LH4003/LH4003C Precision RF Closed Loop Buffer

General Description

The LH4003 is a precision RF buffer optimized for unity gain applications. The LH4003 features a small signal bandwidth of 250 MHz. The buffer is internally compensated to be unity gain stable and has internal short circuit protection. The LH4003 is useful in applications such as video buffering, cable driving, and flash converter input conditioning.

Features

- Operation from $\pm 6V$ supplies
- Drive 50Ω directly
- Internal power supply bypassing
- Short circuit protection
- $1000 V/\mu s$ slew rate
- 0.97 gain accuracy into 50Ω

Applications

- Line drivers
- Video buffers

Note 1: These measurements are taken with the LH4003 strapped for a gain of +1.

Note 2: Tested limits are guaranteed and 100% tested in production.

Note 3: Design limits are guaranteed (but not 100% production tested) over indicated temperature and supply voltage ranges. These limits are not used to calculate outgoing quality levels.

Note 4: Specification is at 25°C junction temperature due to requirements of high speed automatic testing. Actual values at operating temperature will exceed value at $T_J = 25^\circ\text{C}$. See Typical Performance Characteristics for more information.

Note 5: Full power bandwidth is calculated based on slew rate measurement using $\text{FPBW} = \text{slew rate} / (2\pi V_{\text{peak}})$.

Note 6: **Boldface limits are guaranteed over full temperature.** Operating ambient temperature range of LH4003C is -25°C to $+85^\circ\text{C}$, and LH4003 is -55°C to $+125^\circ\text{C}$.

Note 7: When the LH4003 is operated at elevated temperature (such as 125°C), some form of heat sinking or forced air cooling is required. The quiescent power with V_S of $\pm 6V$ is 780 mW, whereas the package is rated to 750 mW without a heatsink at 125°C .

Typical Performance Characteristics

TL/K/9243-2

TL/K/9243-10

TL/K/9243-11

Application Information

The unity gain follower configuration shown in *Figure 1*, offers a 250 MHz small signal bandwidth to the -3dB point and the minimum slew rate of 800 V/ μs insures a full power bandwidth of 65 MHz for a 4V peak-to-peak signal, according to the formula:

$$B = SR / 2\pi V_p$$

Where SR is the slew rate in μs , B is the bandwidth of the device in MHz for a peak sine wave voltage V_p .

The unity gain follower/buffer is therefore an excellent choice for wideband sinewave buffering or pulse amplification. *Figure 2* shows the typical pulse response for such a configuration.

DRIVING CAPACITIVE LOADS

Flash A/D, unterminated cables, etc, can exhibit up to 300 pF of capacitance, thus creating stability or settling problems. *Figure 3* shows the compensation scheme for driving such capacitive loads while still insuring optimum settling. The output current limit of the LH4003 is a considerable help for driving capacitive loads, the charging current is kept in control and the damping resistor can be small without overloading the output stage. A 20 Ω resistor in series with the capacitance is required for insuring an optimum settling time of 0.5% in less than 20 ns which is suitable for driving a 7 bit flash A to D converter in video applications at a sampling rate of 20 MSPS (see *Figure 4*).

LAYOUT CONSIDERATIONS

The layout of a RF/Video PC board where the signal frequency is beyond 100 MHz required special attention. All the traces or connections must be as short and as wide as possible in order to keep their parasitic inductance to a minimum. This is especially critical for the supply lines where the current can reach over 100 mA in a few nanoseconds.

Although the LH4003 contains internal decoupling, it still requires some external bypassing capacitors, which have to be located as close to the supply pins as possible. A 4.7 μF in parallel with a 100 nF low inductance capacitor will insure good filtering. In some cases of noisy environment, or when the power supply is located far from the circuit, it may be necessary to use a dual stage decoupling as shown in *Figure 5*.

Ground can also become a considerable problem. It is assumed to be uniformly zero volts and considered as a reference. In practice, if the ground is poorly laid out, every single point may be at a different potential and at a different phase, which is a source of instability or signal distortion.

The most reliable solution to this problem is to have a ground plane that will minimize the parasitic inductance and therefore, potential and phase differences.

INPUT CAPACITANCE

The input capacitance of the LH4003 is typically 8 pF and will slightly increase with frequency. A large source resistance value in front of this will form a pole, which may substantially reduce the bandwidth of the circuit and affect stability.

This is the reason why resistor values higher than 500 ohms should not be utilized in the feedback network and high source impedance should be avoided.

BIAS CURRENT

The input bias current is typically 100 μA and may create an undesirable output offset voltage when the source impedance is high. An internal 50 Ω resistor is provided for matching with a 50 Ω source impedance in order to minimize the output offset voltage. *Figure 6* shows a circuit that uses a FET transistor pair for the input stage in order to reduce the input bias current to the sub-nanoampere region.

FIGURE 6. FET Buffer Reduces Bias Current

LH4004/LH4004C Wideband FET-Input Buffer/Amplifier

General Description

The LH4004 is an FET input, high speed differential amplifier optimized for unity gain applications. It eliminates most of the drawbacks of conventional open loop buffers and does not require compensation for unity and other low gain operations. It is an ideal choice for video distribution, driving flash converters, and summing amplifiers. Furthermore, the bandwidth does not decrease with increasing gain. At a closed loop gain of 4, the LH4004 still offers a 75 MHz bandwidth.

Features

- ± 0.5 dB gain flatness
- 500 V/ μ s slew rate
- Drives 50 Ω directly
- 140 MHz bandwidth
- No external components required for unity gain operation
- Internal power supply bypassing

Applications

- Unity gain buffer
- Low gain op amp

Note 1: Boldface limits are guaranteed over full temperature range. Operating ambient temperature range of LH4004C is $-25^\circ C$ to $+85^\circ C$, and LH4004 is $-55^\circ C$ to $+125^\circ C$.

Note 2: Tested limits are guaranteed and 100% production tested.

Note 3: Design limits are guaranteed (but not 100% production tested) over the indicated temperature range. These limits are not used to calculate outgoing quality levels.

Note 4: Specification is at $25^\circ C$ junction temperature due to requirements of high speed automatic testing. Actual values at operating temperature will exceed value at $T_J = 25^\circ C$.

Note 5: When the LH4004 is operated at elevated temperature (such as $125^\circ C$), some form of heat sinking or forced air cooling is required. The quiescent power with V_S of $\pm 12V$ is 960 mW, whereas the package is only rated to 800 mW without a heatsink at $125^\circ C$.

Application Hints

The front page figure shows the simplified schematic which includes the feedback resistor and the decoupling capacitors.

The essential difference from other op amps is that both inputs are radically different, the non-inverting input goes to a FET buffer follower and the inverting input is connected to the second stage emitter node. This topology is responsible for the unique bandwidth characteristic and transfer function of the amplifier.

Let's consider the connection diagram of *Figure 1*. The typical transfer function in the case of a classical op amp would be:

$$\frac{V_{OUT}}{V_{IN}} = \frac{K(s)}{1 + K(s)/B}$$

where $B = \frac{R_A + R_B}{R_B}$ and $K(s)$ is the open loop gain of the amplifier and is frequency dependent. By rearranging the formula, we find;

$$(1) \quad \frac{V_{OUT}}{V_{IN}} = B \cdot \frac{K(s)}{K(s) + B}$$

For the LH4004, a small signal analysis shows that the difference between the two inputs turns the previous typical equation into:

$$(2) \quad \frac{V_{OUT}}{V_{IN}} = B \cdot \frac{K(s)}{K(s) + B + m R_A}$$

where m is an internal parameter to the device and $K(s)$ is approximately 70 dB at DC with a 50Ω load.

In both equations, the second term is negligible when the open loop gain of the amplifier, $K(s)$, approaches infinity, but in equation (1), when the signal frequency reaches a point where $K(s)$ is small, say $K(s) = 10$ or less, then the term will be very sensitive to the value of the closed loop gain B and V_{OUT}/V_{IN} will fall earlier as B increases.

In equation (2), m is approximately 0.19 and R_A is provided inside the package, with a value which has been chosen to be 240Ω. The term mR_A is therefore equal to 46 and will dominate the term B as long as it is kept below 5. The result is that V_{OUT}/V_{IN} will not be as dependent on B as with traditional topologies. The gain will still fall with the open loop gain $K(s)$ as the frequency increases, but the roll off will be virtually independent of the closed loop gain B .

Resistor R_B sets the overall closed loop gain, but has very little effect on stability and bandwidth. Another peculiarity of the LH4004 is that the loop compensation can be accomplished by changing the value of resistor R_A (*Figure 2*). Even though this such as settling time, overshoot and phase margin, it will not affect the slew rate. Although this resistive compensation scheme is adequate in most cases, an alternate method is to place a capacitor between pins 3 and 19 (*Figure 3*). This method of compensation also reduces the device slew rate (*Figure 4*).

Low Gain Operation

The small amount of stray capacitance present at the inverting input can cause peaking which increases with decreasing gain. The gain set resistor R_B (in *Figure 1*) is effectively

in parallel with this capacitance and so a frequency domain pole results. With a small R_B , this pole is at a high frequency and it affects the closed loop gain of the LH4004 only slightly. At lower values of gain, this pole becomes significant. For example, at a gain of +2, the gain may peak as much as 1.5 dB to 2 dB at 100 MHz.

LH4006/LH4006C Precision RF Closed Loop Buffer

General Description

The LH4006 is a precision RF buffer optimized for unity gain applications. It features a small signal bandwidth of 350 MHz. The buffer is internally compensated to be unity gain stable and has internal short circuit protection. The LH4006 is useful in applications such as video buffering, cable driving, and flash converter input conditioning. The high bandwidth also allows the LH4006 to be used in RF/IF signal conditioning such as amplification or down conversion.

Features

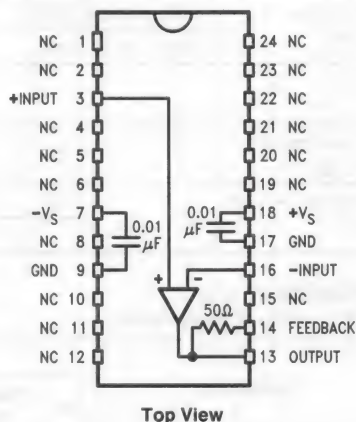

- Operation from $\pm 6V$ supplies
- Drives 50Ω directly

- Internal power supply bypassing
- Short circuit protection
- $1000 V/\mu s$ slew rate
- 0.95 gain accuracy into 50Ω

Applications

- Line drivers
- Video buffers
- Pulse amplifiers

Connection Diagram

TL/K/9255-1

Note 1: NC = not connected.

Note 2: Pins 9 & 17 are internally connected.

Order Number LH4006D & LH4006CD

Typical Performance Characteristics

Application Information

The unity gain follower configuration shown in *Figure 1*, offers a 350 MHz small signal bandwidth to the -3 dB point and the minimum slew rate of 1000 V/ μ s insures a full power bandwidth of 80 MHz for a 4V peak to peak signal, according to the formula:

$$B = \frac{SR}{2 \pi V_p}$$

Where SR is the slew rate in V/ μ s, B is the bandwidth of the device in MHz for a peak sine wave voltage V_p .

The unity gain follower/buffer is therefore an excellent choice for wideband sinewave buffering or pulse amplification. *Figure 2* shows the typical pulse response for such a configuration.

FIGURE 1. Unity Gain Follower

$V_{CC} = \pm 6V$, $R_S = R_L = 50\Omega$.

FIGURE 2. Follower/Buffer Pulse Response

Driving Capacitive Loads

Flash A/D, unterminated cables, etc, can exhibit up to 300 pF of capacitance, thus creating stability or settling problems. Figure 3 shows the compensation scheme for driving such capacitive loads while still insuring optimum settling. The output current limit of the LH4006 is a considerable help for driving capacitive loads, the charging current is kept

in control and the damping resistor can be small without overloading the output stage. A 20 Ω resistor in series with the capacitance is required for insuring an optimum settling time to 0.5% in less than 20 ns which is suitable for driving a 7 bit flash A to D converter in video applications at a sampling rate of 20 MSPS (see Figure 4).

Layout Considerations

The layout of a RF/Video PC board where the signal frequency is beyond 100 MHz requires special attention. All the traces or connections must be as short and as wide as possible in order to keep their parasitic inductance to a minimum. This is especially critical for the supply lines where the current can reach over 100 mA in a few nanoseconds.

Although the LH4006 contains internal decoupling, it still requires some external bypassing capacitors, which have to be located as close to the supply pins as possible. A $4.7\ \mu\text{F}$ in parallel with a $100\ \text{nF}$ low inductance capacitor will insure good filtering. In some cases of noisy environment, or when the power supply is located far from the circuit, it may be necessary to use a dual stage decoupling as shown in *Figure 5*.

TL/K/9255-8

FIGURE 5. Dual Stage Decoupling

Ground can also become a considerable problem. It is assumed to be uniformly zero volts and considered as a reference. In practice, if the ground is poorly laid out, every single point may be at a different potential and at a different phase, which is a source of instability or signal distortion.

The most reliable solution to this problem is to have a ground plane that will minimize the parasitic inductance and therefore, potential and phase differences.

Input Capacitance

The input capacitance of the LH4006 is typically $8\ \text{pF}$ and will slightly increase with frequency. A large source resistance value in front of this will form a pole, which may substantially reduce the bandwidth of the circuit and affect stability.

This is the reason why resistor values higher than $500\ \Omega$ should not be used in the feedback network and high source impedance should be avoided.

Bias Current

The input bias current is typically $100\ \mu\text{A}$ and may create an undesirable output offset voltage when the source impedance is high. An internal $50\ \Omega$ resistor is provided for matching with a $50\ \Omega$ source impedance in order to minimize the output offset voltage. *Figure 6* shows a circuit that uses a FET transistor pair for the input stage in order to reduce the input bias current to the sub-nanoampere region.

TL/K/9255-9

FIGURE 6. FET Input Follower Buffer

LM102/LM302 Voltage Followers

General Description

The LM102 series are high-gain operational amplifiers designed specifically for unity-gain voltage follower applications. Built on a single silicon chip, the devices incorporate advanced processing techniques to obtain very low input current and high input impedance. Further, the input transistors are operated at zero collector-base voltage to virtually eliminate high temperature leakage currents. It can therefore be operated in a temperature stabilized component oven to get extremely low input currents and low offset voltage drift.

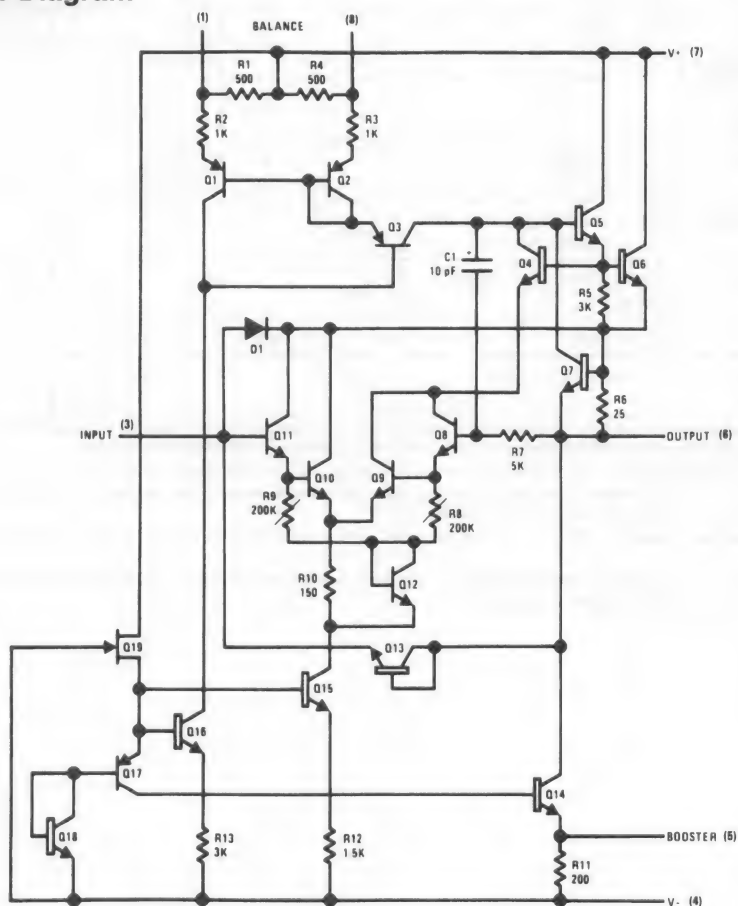

The LM102, which is designed to operate with supply voltages between $\pm 12\text{V}$ and $\pm 15\text{V}$, also features low input capacitance as well as excellent small signal and large signal frequency response—all of which minimize high fre-

quency gain error. Because of the low wiring capacitances inherent in monolithic construction, this fast operation can be realized without increasing power consumption.

Features

- Fast slewing — $10\text{V}/\mu\text{s}$
- Low input current — 10 nA (max)
- High input resistance — $10,000\text{ M}\Omega$
- No external frequency compensation required
- Simple offset balancing with optional 1K potentiometer
- Plug-in replacement for both the LM101 and LM709 in voltage follower applications

Supply Current	$T_A = 25^\circ\text{C}$		2.6	4.0				mA
Supply Voltage Rejection Ratio	$\pm 12\text{V} \leq V_S \leq \pm 15\text{V}$	60			60			dB

Note 1: The maximum junction temperature of the LM102 is 150°C, while that of the LM302 is 85°C. For operating at elevated temperatures, devices in the TO-5 package must be derated based on a thermal resistance of 150°C/W, junction to ambient, or 45°C/W, junction to case.

Note 2: For supply voltages less than ±15V, the absolute maximum input voltage is equal to the supply voltage.

Note 3: It is necessary to insert a resistor (at least 5k and preferably 10k) in series with the input pin when the amplifier is driven from low impedance sources to prevent damage when the output is shorted and to ensure stability.

Note 4: These specifications apply for $\pm 12\text{V} \leq V_S \leq \pm 15\text{V}$ and $-55^\circ\text{C} \leq T_A \leq 125^\circ\text{C}$ for the LM102 and $0^\circ\text{C} \leq T_A \leq 70^\circ\text{C}$ for the LM302 unless otherwise specified.

Note 5: Increased output swing under load can be obtained by connecting an external resistor between the booster and V^- terminals. See curve.

Note 6: Refer to RETS102X for the LM102H military specifications.

LM110/LM210/LM310 Voltage Follower

General Description

The LM110 series are monolithic operational amplifiers internally connected as unity-gain non-inverting amplifiers. They use super-gain transistors in the input stage to get low bias current without sacrificing speed. Directly interchangeable with 101, 741 and 709 in voltage follower applications, these devices have internal frequency compensation and provision for offset balancing.

The LM110 series are useful in fast sample and hold circuits, active filters, or as general-purpose buffers. Further, the frequency response is sufficiently better than standard IC amplifiers that the followers can be included in the feedback loop without introducing instability. They are plug-in replacements for the LM102 series voltage followers, offer-

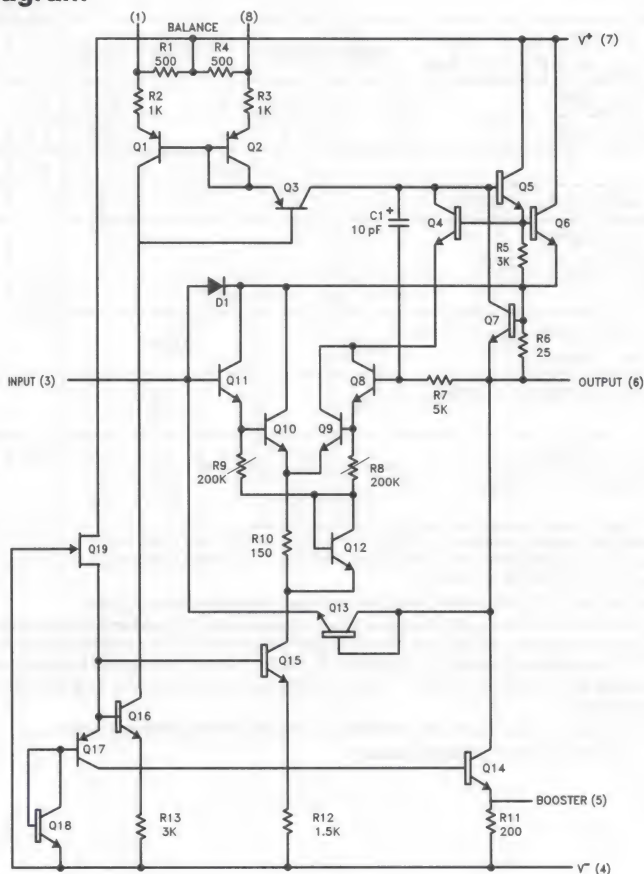

ing lower offset voltage, drift, bias current and noise in addition to higher speed and wider operating voltage range.

The LM110 is specified over a temperature range $-55^{\circ}\text{C} \leq T_A \leq +125^{\circ}\text{C}$, the LM210 from $-25^{\circ}\text{C} \leq T_A \leq +85^{\circ}\text{C}$ and the LM310 from $0^{\circ}\text{C} \leq T_A \leq +70^{\circ}\text{C}$.

Features

- Input current 10 nA max over temperature
- Small signal bandwidth 20 MHz
- Slew rate 30 V/ μs
- Supply voltage range $\pm 5\text{V}$ to $\pm 18\text{V}$

ESD rating to be determined.

Electrical Characteristics (Note 4)

Parameter	Conditions	LM110			LM210			LM310			Units
		Min	Typ	Max	Min	Typ	Max	Min	Typ	Max	
Input Offset Voltage	$T_A = 25^\circ\text{C}$		1.5	4.0		1.5	4.0		2.5	7.5	mV
Input Bias Current	$T_A = 25^\circ\text{C}$		1.0	3.0		1.0	3.0		2.0	7.0	nA
Input Resistance	$T_A = 25^\circ\text{C}$	10^{10}	10^{12}		10^{10}	10^{12}		10^{10}	10^{12}		Ω
Input Capacitance			1.5			1.5			1.5		pF
Large Signal Voltage Gain	$T_A = 25^\circ\text{C}$, $V_S = \pm 15\text{V}$ $V_{OUT} = \pm 10\text{V}$, $R_L = 8\text{ k}\Omega$	0.999	0.9999		0.999	0.9999		0.999	0.9999		V/V
Output Resistance	$T_A = 25^\circ\text{C}$		0.75	2.5		0.75	2.5		0.75	2.5	Ω
Supply Current	$T_A = 25^\circ\text{C}$		3.9	5.5		3.9	5.5		3.9	5.5	mV
Input Offset Voltage				6.0			6.0			10	mV
Offset Voltage	$-55^\circ\text{C} \leq T_A \leq +85^\circ\text{C}$		6			6					$\mu\text{V}/^\circ\text{C}$
Temperature Drift	$T_A = 125^\circ\text{C}$ $0^\circ\text{C} \leq T_A \leq +70^\circ\text{C}$		12			12			10		$\mu\text{V}/^\circ\text{C}$ $\mu\text{V}/^\circ\text{C}$
Input Bias Current				10			10			10	nA
Large Signal Voltage Gain	$V_S = \pm 15\text{V}$, $V_{OUT} = \pm 10\text{V}$ $R_L = 10\text{ k}\Omega$	0.999			0.999			0.999			V/V
Output Voltage Swing (Note 5)	$V_S = \pm 15\text{V}$, $R_L = 10\text{ k}\Omega$	±10			±10			±10			V
Supply Current	$T_A = 125^\circ\text{C}$		2.0	4.0		2.0	4.0				mA
Supply Voltage Rejection Ratio	$\pm 5\text{V} \leq V_S \leq \pm 18\text{V}$	70	80		70	80		70	80		dB

Note 1: The maximum junction temperature of the LM110 is 150°C, of the LM210 is 100°C, and of the LM310 is 85°C. For operating at elevated temperatures, devices in the TO-5 package must be derated based on a thermal resistance of 150°C/W, junction to ambient, or 45°C/W, junction to case. The thermal resistance of the dual-in-line package is 100°C/W, junction to ambient.

Note 2: For supply voltages less than ±15V, the absolute maximum input voltage is equal to the supply voltage.

Note 3: Continuous short circuit for the LM110 and LM210 is allowed for case temperatures to 125°C and ambient temperatures to 70°C, and for the LM310, 70°C case temperature or 55°C ambient temperature. It is necessary to insert a resistor greater than 2 k Ω in series with the input when the amplifier is driven from low impedance sources to prevent damage when the output is shorted. $R_S = 5\text{ k}\Omega$ min, 14k typical is recommended for dynamic stability in all applications.

Note 4: These specifications apply for $\pm 5\text{V} \leq V_S \leq \pm 18\text{V}$ and $-55^\circ\text{C} \leq T_A \leq 125^\circ\text{C}$ for the LM110, $-25^\circ\text{C} \leq T_A \leq 85^\circ\text{C}$ for the LM210, and $0^\circ\text{C} \leq T_A \leq 70^\circ\text{C}$ for the LM310 unless otherwise specified.

Note 5: Increased output swing under load can be obtained by connecting an external resistor between the booster and V^- terminals. See curve.

Note 6: Refer to RETS110X for LM110H, LM110J military specifications.

LM6113/LM6214/LM6314 High Speed Op Amp Plus Power Buffer

General Description

The LM6113 family is a combined high speed op amp and power buffer. The op amp features a 40 MHz small signal bandwidth, and a fast 240V/ μ s slew rate. A compensation pin is included for altering the open loop bandwidth and slew rate if desired. The op amp and buffer are pinned out separately, and can be used independently or in combination. The buffer has a 50 MHz small signal bandwidth and slews at 700V/ μ s into a 50 Ω load and can deliver ± 300 mA output current. The buffer includes protection in the form of current limit and thermal shutdown. The 16 pin plastic version, (LM6214/LM6314), has the unique features of electronic shutdown and error flag included.

These amplifiers are built with National's new VIPTM (Vertically Integrated PNP) process which provides fast PNP transistors that are true complements to the already fast NPN devices. This advanced junction-isolated process delivers high speed performance without the need for complex and expensive dielectric isolation.

Features

- Current and thermal limiting
- Op amp and buffer pinned out separately

Op Amp

- Wide bandwidth 40 MHz
- High slew rate 240V/ μ s

Buffer

- High slew rate (Into 50 Ω) 700V/ μ s
- Wide bandwidth 50 MHz
- Electronic shutdown
- Bi-State Output
- Error flag warns of faults

LM6121/LM6221/LM6321 High Speed Buffer

General Description

The LM6121 family of high speed unity gain buffers slew at $800 \text{ V}/\mu\text{s}$ and have a small signal bandwidth of 50 MHz while driving a 50Ω load. These buffers can deliver $\pm 300 \text{ mA}$, and do not oscillate while driving large capacitive loads. The LM6121 features performance which is superior to the LH0002 with the additional features of current limit and thermal shutdown.

These buffers are built with National's new VIP™ (Vertically Integrated PNP) process which provides fast PNP transistors that are true compliments to the already fast NPN devices. This advanced junction-isolated process delivers high speed performance without the need for complex and expensive dielectric isolation.

Features

- High Slew Rate (into 50Ω) $800 \text{ V}/\mu\text{s}$
- Wide Bandwidth (into 50Ω) 50 MHz
- Peak Output Current $\pm 300 \text{ mA}$
- High Input Impedance 5 M Ω
- LH0002H pin compatible
- No oscillations with Capacitive loads
- 5V to $\pm 16\text{V}$ operation
- Current and Thermal Limiting
- Slew Rate 100% tested

Simplified Schematic

LM6125/LM6225/LM6325 High Speed Buffer

General Description

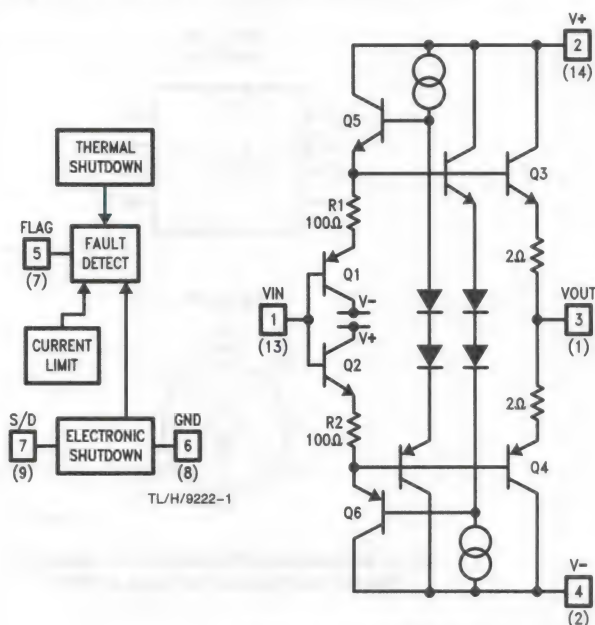

The LM6125 family of high speed unity gain buffers slew at $800 \text{ V}/\mu\text{s}$ and have a small signal bandwidth of 50 MHz while driving a 50Ω load. These buffers can drive $\pm 300 \text{ mA}$, and do not oscillate while driving large capacitive loads. The LM6125 contains unique features not found in power buffers, these include: current limit, thermal shutdown, electronic shutdown, and an error flag that warns of fault conditions.

These buffers are built with National's new VIPTM (Vertically Integrated PNP) process which provides fast PNP transistors that are true compliments to the already fast NPN devices. This advanced junction-isolated process delivers high-speed performance without the need for complex and expensive dielectric isolation.

Features

- High slew rate (into 50Ω) $800 \text{ V}/\mu\text{s}$
- Wide bandwidth (into 50Ω) 50 MHz
- Peak output current $\pm 300 \text{ mA}$
- High input impedance $5 \text{ M}\Omega$
- No oscillations with capacitive loads
- Current and thermal limiting
- Electronic shutdown
- Bi-state output
- Error flag warns of faults
- Slew rate 100% tested

Simplified Schematic

Numbers in () are for 14 pin N DIP.

Voltage Comparators Definition of Terms

Input Bias Current: The average of the two input currents.

Input Offset Current: The absolute value of the difference between the two input currents for which the output will be driven higher than or lower than specified voltages.

Input Offset Voltage: The absolute value of the voltage between the input terminals required to make the output voltage greater than or less than specified voltages.

Input Voltage Range: The range of voltage on the input terminals (common-mode) over which the offset specifications apply.

Logic Threshold Voltage: The voltage at the output of the comparator at which the loading logic circuitry changes its digital state.

Negative Output Level: The negative DC output voltage with the comparator saturated by a differential input equal to or greater than a specified voltage.

Output Leakage Current: The current into the output terminal with the output voltage within a given range and the input drive equal to or greater than a given value.

Output Resistance: The resistance seen looking into the output terminal with the DC output level at the logic threshold voltage.

Output Sink Current: The maximum negative current that can be delivered by the comparator.

Positive Output Level: The high output voltage level with a given load and the input drive equal to or greater than a specified value.

Power Consumption: The power required to operate the comparator with no output load. The power will vary with signal level, but is specified as a maximum for the entire range of input signal conditions.

Response Time: The interval between the application of an input step function and the time when the output crosses the logic threshold voltage. The input step drives the comparator from some initial, saturated input voltage to an input level just barely in excess of that required to bring the output from saturation to the logic threshold voltage. This excess is referred to as the voltage overdrive.

Saturation Voltage: The low-output voltage level with the input drive equal to or greater than a specified value.

Strobe Current: The current out of the strobe terminal when it is at the zero logic level.

Strobe Output Level: The DC output voltage, independent of input conditions, with the voltage on the strobe terminal equal to or less than the specified low state.

Strobe "ON" Voltage: The maximum voltage on either strobe terminal required to force the output to the specified high state independent of the input voltage.

Strobe "OFF" Voltage: The minimum voltage on the strobe terminal that will guarantee that it does not interfere with the operation of the comparator.

Strobe Release Time: The time required for the output to rise to the logic threshold voltage after the strobe terminal has been driven from zero to the one logic level.

Supply Current: The current required from the positive or negative supply to operate the comparator with no output load. The power will vary with input voltage, but is specified as a maximum for the entire range of input voltage conditions.

Voltage Gain: The ratio of the change in output voltage to the change in voltage between the input terminals producing it.

Note 1: Datasheet should be referred to for test conditions and more detailed information.

Note 2: This selection guide should be used to select for Response Time required. Industrial and Military Temperature Range types are available. The DC specs are for the lowest Commercial Grade available.

LF111/LF211/LF311 Voltage Comparators

General Description

The LF111, LF211 and LF311 are FET input voltage comparators that virtually eliminate input current errors. Designed to operate over a 5.0V to ± 15 V range the LF111 can be used in the most critical applications.

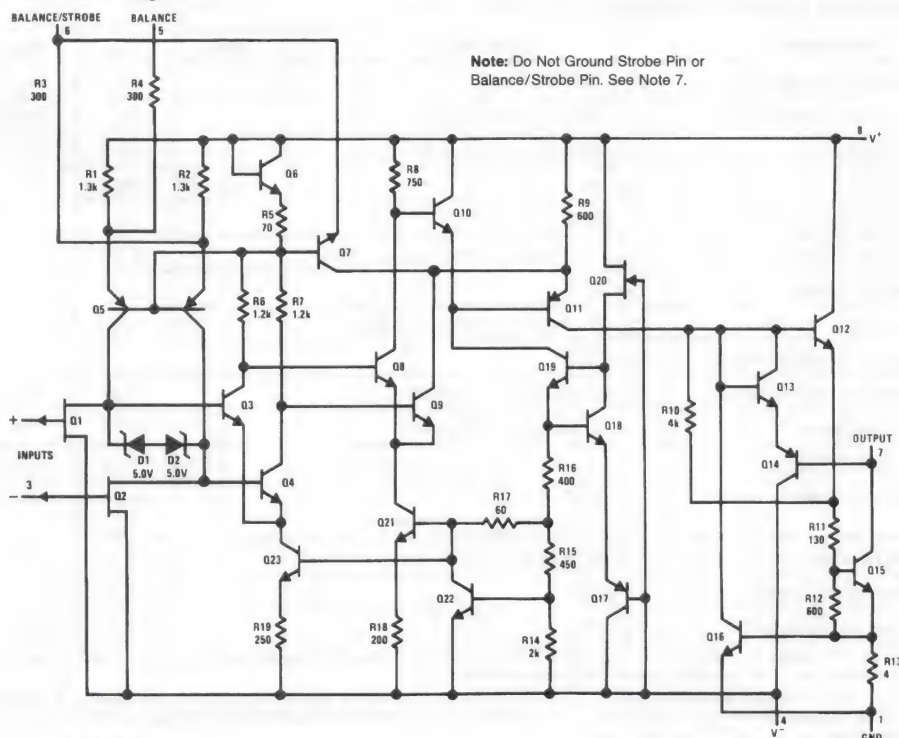

The extremely low input currents of the LF111 allows the use of a simple comparator in applications usually requiring input current buffering. Leakage testing, long time delay circuits, charge measurements, and high source impedance voltage comparisons are easily done.

Further, the LF111 can be used in place of the LM111 eliminating errors due to input currents. See the "application hints" of the LM311 for application help.

Features

- Eliminates input current errors
- Interchangeable with LM111
- No need for input current buffering

Electrical Characteristics (LF111/LF211) (Note 3)

Parameter	Conditions	Min	Typ	Max	Units
Input Offset Voltage (Note 4)	$T_A = 25^{\circ}\text{C}$, $R_S \leq 50k$		0.7	4.0	mV
Input Offset Current (Note 4)	$T_A = 25^{\circ}\text{C}$, $V_{CM} = 0$ (Note 6)		5.0	25	pA
Input Bias Current	$T_A = 25^{\circ}\text{C}$, $V_{CM} = 0$ (Note 6)		20	50	pA
Voltage Gain	$T_A = 25^{\circ}\text{C}$	40	200		V/mV
Response Time (Note 5)	$T_A = 25^{\circ}\text{C}$		200		ns
Saturation Voltage	$V_{IN} \leq -5.0\text{ mV}$, $I_{OUT} = 50\text{ mA}$, $T_A = 25^{\circ}\text{C}$		0.75	1.5	V
Strobe On Current	$T_A = 25^{\circ}\text{C}$		3.0		mA
Output Leakage Current	$V_{IN} \leq 5.0\text{ mV}$, $V_{OUT} = 35V$, $T_A = 25^{\circ}\text{C}$		0.2	10	nA
Input Offset Voltage (Note 4)	$R_S \leq 50k$			6.0	mV
Input Offset Current (Note 4)	$V_S = \pm 15V$, $V_{CM} = 0$ (Note 6)		2.0	3.0	nA
Input Bias Current	$V_S = \pm 15V$, $V_{CM} = 0$ (Note 6)		5.0	7.0	nA
Input Voltage Range		-13.5	± 14	13.0	V
Saturation Voltage	$V^+ \geq 4.5V$, $V^- = 0$ $V_{IN} \leq -6.0\text{ mV}$, $I_{SINK} \leq 8.0\text{ mA}$		0.23	0.4	V
Output Leakage Current	$V_{IN} \geq 5.0\text{ mV}$, $V_{OUT} = 35V$		0.1	0.5	μA
Positive Supply Current	$T_A = 25^{\circ}\text{C}$		5.1	6.0	mA
Negative Supply Current	$T_A = 25^{\circ}\text{C}$		4.1	5.0	mA

Note 1: This rating applies for $\pm 15V$ supplies. The positive input voltage limit is 30V above the negative supply. The negative input voltage limit is equal to the negative supply voltage or 30V below the positive supply, whichever is less.

Note 2: The maximum junction temperature of the LF111 is $+150^{\circ}\text{C}$, the LF211 is $+110^{\circ}\text{C}$ and the LF311 is $+85^{\circ}\text{C}$. For operating at elevated temperatures, devices in the TO-5 package must be derated based on a thermal resistance of $+74^{\circ}\text{C/W}$ junction to ambient (in 400 linear feet/min air flow), $+225^{\circ}\text{C/W}$ junction to ambient (in static air), or $+23^{\circ}\text{C/W}$ junction to case.

Note 3: These specifications apply for $V_S = \pm 15V$, and the Ground pin at ground, and $-55^{\circ}\text{C} \leq T_A \leq +125^{\circ}\text{C}$ for the LF111, unless otherwise stated. With the LF211, however, all temperature specifications are limited to $-25^{\circ}\text{C} \leq T_A \leq +85^{\circ}\text{C}$ and for the LF311 $0^{\circ}\text{C} \leq T_A \leq +70^{\circ}\text{C}$. The offset voltage, offset current and bias current specifications apply for any supply voltage from a single 5.0V supply up to $\pm 15V$ supplies.

Note 4: The offset voltages and offset currents given are the maximum values required to drive the output within a volt of either supply with a 1.0 mA load. Thus, these parameters define an error band and take into account the worst case effects of voltage gain and input impedance.

Note 5: The response time specified (see definitions) is for a 100 mV input step with 5.0 mV overdrive.

Note 6: For input voltages greater than 15V above the negative supply the bias and offset currents will increase—see typical performance curves.

Note 7: Do not short the strobe pin to ground; it should be current driven at 3 to 5 mA.

Note 8: Refer to RETSF111X for LF111H military specifications.

Electrical Characteristics (LF311) (Note 3)

Parameter	Conditions	Min	Typ	Max	Units
Input Offset Voltage (Note 4)	$T_A = 25^\circ\text{C}$, $R_S \leq 50\text{k}$		2.0	10	mV

Input Bias Current	$V_S = 15\text{V}$, $V_{CM} = 0$ (Note 6)		3.0		nA
Input Voltage Range			+ 14 - 13.5		V V
Saturation Voltage	$V^+ \geq 4.5\text{V}$, $V^- = 0$ $V_{IN} \leq -10\text{ mV}$, $I_{SINK} \leq 8.0\text{ mA}$		0.23	0.4	V
Positive Supply Current	$T_A = 25^\circ\text{C}$		5.1	7.5	mA
Negative Supply Current	$T_A = 25^\circ\text{C}$		4.1	5.0	mA

Note 1: This rating applies for $\pm 15\text{V}$ supplies. The positive input voltage limit is 30V above the negative supply. The negative input voltage limit is equal to the negative supply voltage or 30V below the positive supply, whichever is less.

Note 2: The maximum junction temperature of the LF111 is $+150^\circ\text{C}$, the LF211 is $+110^\circ\text{C}$ and the LF311 is $+85^\circ\text{C}$. For operating at elevated temperatures, devices in the TO-5 package must be derated based on a thermal resistance of $+150^\circ\text{C/W}$, junction to ambient, or $+45^\circ\text{C/W}$, junction to case.

Note 3: These specifications apply for $V_S = \pm 15\text{V}$ and $-55^\circ\text{C} \leq T_A \leq +125^\circ\text{C}$ for the LF111, unless otherwise stated. With the LF211, however, all temperature specifications are limited to $-25^\circ\text{C} \leq T_A \leq +85^\circ\text{C}$ and for the LF311 $0^\circ\text{C} \leq T_A \leq +70^\circ\text{C}$. The offset voltage, offset current and bias current specifications apply for any supply voltage from a single 5.0 mV supply up to $\pm 15\text{V}$ supplies.

Note 4: The offset voltages and offset currents given are the maximum values required to drive the output within a volt of either supply with a 1.0 mA load. Thus, these parameters define an error band and take into account the worst case effects of voltage gain and input impedance.

Note 5: The response time specified (see definitions) is for a 100 mV input step with 5.0 mV overdrive.

Note 6: For input voltages greater than 15V above the negative supply the bias and offset currents will increase—see typical performance curves.

Note 7: Do not short the strobe pin to ground; it should be current driven at 3 to 5 mA.

LM106/LM206/LM306 Voltage Comparator

General Description

The LM106 series are high-speed voltage comparators designed to accurately detect low-level analog signals and drive a digital load. They are equivalent to an LM710, combined with a two input NAND gate and an output buffer. The circuits can drive RTL, DTL or TTL integrated circuits directly. Furthermore, their outputs can switch voltages up to 24V at currents as high as 10 mA.

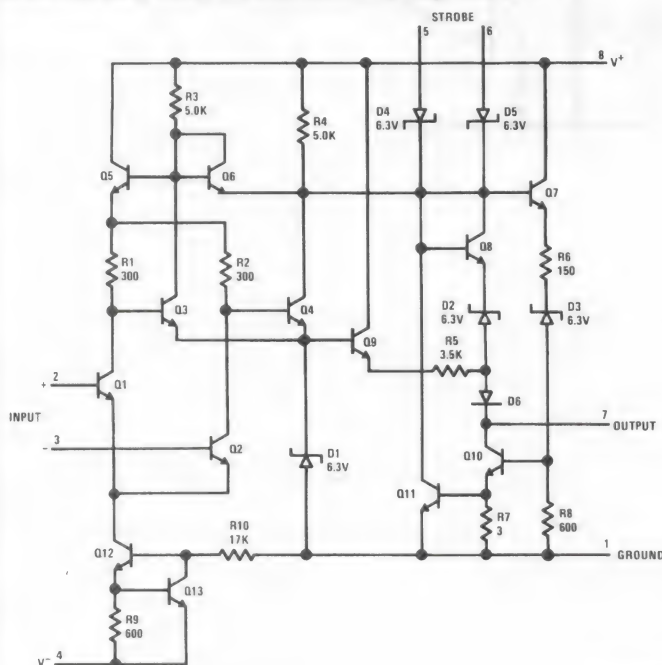

The devices have short-circuit protection which limits the inrush current when it is used to drive incandescent lamps, in addition to preventing damage from accidental shorts to the positive supply. The speed is equivalent to that of an LM710. However, they are even faster where buffers and additional logic circuitry can be eliminated by the increased flexibility of the LM106 series. They can also be operated from any negative supply voltage between $-3V$ and $-12V$ with little effect on performance.

The LM106 is specified for operation over the $-55^{\circ}C$ to $+125^{\circ}C$ military temperature range. The LM206 is specified for operation over the $-25^{\circ}C$ to $+85^{\circ}C$ temperature range. The LM306 is specified for operation over $0^{\circ}C$ to $+70^{\circ}C$ temperature range.

Features

- Improved accuracy
- Fan-out of 10 with DTL or TTL
- Added logic or strobe capability
- Useful as a relay or lamp driver
- Plug-in replacement for the LM710
- 40 ns maximum response time

LM111/LM211/LM311 Voltage Comparator

General Description

The LM111, LM211 and LM311 are voltage comparators that have input currents nearly a thousand times lower than devices like the LM106 or LM710. They are also designed to operate over a wider range of supply voltages: from standard $\pm 15V$ op amp supplies down to the single 5V supply used for IC logic. Their output is compatible with RTL, DTL and TTL as well as MOS circuits. Further, they can drive lamps or relays, switching voltages up to 50V at currents as high as 50 mA.

Both the inputs and the outputs of the LM111, LM211 or the LM311 can be isolated from system ground, and the output can drive loads referred to ground, the positive supply or the negative supply. Offset balancing and strobe capability are provided and outputs can be wire OR'ed. Although slower than the LM106 and LM710 (200 ns response time vs

40 ns) the devices are also much less prone to spurious oscillations. The LM111 has the same pin configuration as the LM106 and LM710.

The LM211 is identical to the LM111, except that its performance is specified over a $-25^{\circ}C$ to $+85^{\circ}C$ temperature range instead of $-55^{\circ}C$ to $+125^{\circ}C$. The LM311 has a temperature range of $0^{\circ}C$ to $+70^{\circ}C$.

Features

- Operates from single 5V supply
- Input current: 150 nA max. over temperature
- Offset current: 20 nA max. over temperature
- Differential input voltage range: $\pm 30V$
- Power consumption: 135 mW at $\pm 15V$

Typical Applications**

**Note: Pin connections shown on schematic diagram and typical applications are for TO-5 package.

Offset Balancing

Strobing

Note: Do Not Ground Strobe Pin.

Increasing Input Stage Current*

*Increases typical common mode slew from $7.0V/\mu s$ to $18V/\mu s$.

Detector for Magnetic Transducer

Relay Driver with Strobe

*Absorbs inductive kickback of relay and protects IC from severe voltage transients on $V+$ line.

Note: Do Not Ground Strobe Pin.

Digital Transmission Isolator

Strobing off Both Input* and Output Stages

*Typical input current is 50 pA with inputs strobed off.

Note: Do Not Ground Strobe Pin.

Output Leakage Current	$V_{IN} \geq 5 \text{ mV}$, $V_{OUT} = 35V$ $T_A = 25^{\circ}\text{C}$, $I_{STROBE} = 3 \text{ mA}$		0.2	10	nA
Input Offset Voltage (Note 4)	$R_S \leq 50 k$			4.0	mV
Input Offset Current (Note 4)				20	nA
Input Bias Current				150	nA
Input Voltage Range	$V^{+} = 15V$, $V^{-} = -15V$, Pin 7 Pull-Up May Go To 5V	-14.5	13.8,-14.7	13.0	V
Saturation Voltage	$V^{+} \geq 4.5V$, $V^{-} = 0$ $V_{IN} \leq -6 \text{ mV}$, $I_{SINK} \leq 8 \text{ mA}$		0.23	0.4	V
Output Leakage Current	$V_{IN} \geq 5 \text{ mV}$, $V_{OUT} = 35V$		0.1	0.5	μA
Positive Supply Current	$T_A = 25^{\circ}\text{C}$		5.1	6.0	mA
Negative Supply Current	$T_A = 25^{\circ}\text{C}$		4.1	5.0	mA

Note 1: This rating applies for ± 15 supplies. The positive input voltage limit is 30V above the negative supply. The negative input voltage limit is equal to the negative supply voltage or 30V below the positive supply, whichever is less.

Note 2: The maximum junction temperature of the LM111 is 150°C , while that of the LM211 is 110°C . For operating at elevated temperatures, devices in the TO-5 package must be derated based on a thermal resistance of $150^{\circ}\text{C}/\text{W}$, junction to ambient, or $45^{\circ}\text{C}/\text{W}$, junction to case. The thermal resistance of the dual-in-line package is $110^{\circ}\text{C}/\text{W}$, junction to ambient.

Note 3: These specifications apply for $V_S = \pm 15V$ and Ground pin at ground, and $-55^{\circ}\text{C} \leq T_A \leq +125^{\circ}\text{C}$, unless otherwise stated. With the LM211, however, all temperature specifications are limited to $-25^{\circ}\text{C} \leq T_A \leq +85^{\circ}\text{C}$. The offset voltage, offset current and bias current specifications apply for any supply voltage from a single 5V supply up to $\pm 15V$ supplies.

Note 4: The offset voltages and offset currents given are the maximum values required to drive the output within a volt of either supply with a 1 mA load. Thus, these parameters define an error band and take into account the worst-case effects of voltage gain and input impedance.

Note 5: The response time specified (see definitions) is for a 100 mV input step with 5 mV overdrive.

Note 6: Do not short the strobe pin to ground; it should be current driven at 3 to 5 mA.

Note 7: Refer to RETS111X for the LM111H, LM111J and LM111J-8 military specifications.

Absolute Maximum Ratings for the LM311

If Military/Aerospace specified devices are required, contact the National Semiconductor Sales Office/Distributors for availability and specifications.

Application Hints

CIRCUIT TECHNIQUES FOR AVOIDING OSCILLATIONS IN COMPARATOR APPLICATIONS

When a high-speed comparator such as the LM111 is used with fast input signals and low source impedances, the output response will normally be fast and stable, assuming that the power supplies have been bypassed (with 0.1 μ F disc capacitors), and that the output signal is routed well away from the inputs (pins 2 and 3) and also away from pins 5 and 6.

However, when the input signal is a voltage ramp or a slow sine wave, or if the signal source impedance is high (1 k Ω to 100 k Ω), the comparator may burst into oscillation near the crossing-point. This is due to the high gain and wide bandwidth of comparators like the LM111. To avoid oscillation or instability in such a usage, several precautions are recommended, as shown in *Figure 1* below.

1. The trim pins (pins 5 and 6) act as unwanted auxiliary inputs. If these pins are not connected to a trim-pot, they should be shorted together. If they are connected to a trim-pot, a 0.01 μ A capacitor C1 between pins 5 and 6 will minimize the susceptibility to AC coupling. A smaller capacitor is used if pin 5 is used for positive feedback as in *Figure 1*.
2. Certain sources will produce a cleaner comparator output waveform if a 100 pF to 1000 pF capacitor C2 is connected directly across the input pins.
3. When the signal source is applied through a resistive network, R_S , it is usually advantageous to choose an R_S of substantially the same value, both for DC and for dynamic (AC) considerations. Carbon, tin-oxide, and metal-film resistors have all been used successfully in comparator input circuitry. Inductive wirewound resistors are not suitable.

4. When comparator circuits use input resistors (eg. summing resistors), their value and placement are particularly important. In all cases the body of the resistor should be close to the device or socket. In other words there should be very little lead length or printed-circuit foil run between comparator and resistor to radiate or pick up signals. The same applies to capacitors, pots, etc. For example, if $R_S = 10$ k Ω , as little as 5 inches of lead between the resistors and the input pins can result in oscillations that are very hard to damp. Twisting these input leads tightly is the only (second best) alternative to placing resistors close to the comparator.

5. Since feedback to almost any pin of a comparator can result in oscillation, the printed-circuit layout should be engineered thoughtfully. Preferably there should be a groundplane under the LM111 circuitry, for example, one side of a double-layer circuit card. Ground foil (or, positive supply or negative supply foil) should extend between the output and the inputs, to act as a guard. The foil connections for the inputs should be as small and compact as possible, and should be essentially surrounded by ground foil on all sides, to guard against capacitive coupling from any high-level signals (such as the output). If pins 5 and 6 are not used, they should be shorted together. If they are connected to a trim-pot, the trim-pot should be located, at most, a few inches away from the LM111, and the 0.01 μ F capacitor should be installed. If this capacitor cannot be used, a shielding printed-circuit foil may be advisable between pins 6 and 7. The power supply bypass capacitors should be located within a couple inches of the LM111. (Some other comparators require the power-supply bypass to be located immediately adjacent to the comparator.)

TL/H/5704-29

FIGURE 1. Improved Positive Feedback

Application Hints (Continued)

6. It is a standard procedure to use hysteresis (positive feedback) around a comparator, to prevent oscillation, and to avoid excessive noise on the output because the comparator is a good amplifier for its own noise. In the circuit of *Figure 2*, the feedback from the output to the positive input will cause about 3 mV of hysteresis. However, if R_S is larger than 100Ω , such as $50\text{ k}\Omega$, it would not be reasonable to simply increase the value of the positive feedback resistor above $510\text{ k}\Omega$. The circuit of *Figure 3* could be used, but it is rather awkward. See the notes in paragraph 7 below.
7. When both inputs of the LM111 are connected to active signals, or if a high-impedance signal is driving the positive input of the LM111 so that positive feedback would be disruptive, the circuit of *Figure 1* is ideal. The positive

feedback is to pin 5 (one of the offset adjustment pins). It is sufficient to cause 1 to 2 mV hysteresis and sharp transitions with input triangle waves from a few Hz to hundreds of kHz. The positive-feedback signal across the 82Ω resistor swings 240 mV below the positive supply. This signal is centered around the nominal voltage at pin 5, so this feedback does not add to the V_{OS} of the comparator. As much as 8 mV of V_{OS} can be trimmed out, using the $5\text{ k}\Omega$ pot and $3\text{ k}\Omega$ resistor as shown.

8. These application notes apply specifically to the LM111, LM211, LM311, and LF111 families of comparators, and are applicable to all high-speed comparators in general, (with the exception that not all comparators have trim pins).

LM119/LM219/LM319 High Speed Dual Comparator

General Description

The LM119 series are precision high speed dual comparators fabricated on a single monolithic chip. They are designed to operate over a wide range of supply voltages down to a single 5V logic supply and ground. Further, they have higher gain and lower input currents than devices like the LM710. The uncommitted collector of the output stage makes the LM119 compatible with RTL, DTL and TTL as well as capable of driving lamps and relays at currents up to 25 mA.

Features

- Two independent comparators
- Operates from a single 5V supply
- Typically 80 ns response time at $\pm 15V$

- Minimum fan-out of 2 each side
- Maximum input current of $1 \mu A$ over temperature
- Inputs and outputs can be isolated from system ground
- High common mode slew rate

Although designed primarily for applications requiring operation from digital logic supplies, the LM119 series are fully specified for power supplies up to $\pm 15V$. It features faster response than the LM111 at the expense of higher power dissipation. However, the high speed, wide operating voltage range and low package count make the LM119 much more versatile than older devices like the LM711.

The LM119 is specified from $-55^{\circ}C$ to $+125^{\circ}C$, the LM219 is specified from $-25^{\circ}C$ to $+85^{\circ}C$, and the LM319 is specified from $0^{\circ}C$ to $+70^{\circ}C$.

Electrical Characteristics (Note 3) LM119/LM219

Parameter	Conditions	Min	Typ	Max	Units
Input Offset Voltage (Note 4)	$T_A = 25^\circ\text{C}$, $R_S \leq 5\text{k}$		0.7	4.0	mV
Input Offset Current (Note 4)	$T_A = 25^\circ\text{C}$		30	75	nA
Input Bias Current	$T_A = 25^\circ\text{C}$		150	500	nA
Voltage Gain	$T_A = 25^\circ\text{C}$ (Note 6)	10	40		V/mV
Response Time (Note 5)	$T_A = 25^\circ\text{C}$, $V_S = \pm 15\text{V}$		80		ns
Saturation Voltage	$V_{IN} \leq -5\text{ mV}$, $I_{OUT} = 25\text{ mA}$ $T_A = 25^\circ\text{C}$		0.75	1.5	V
Output Leakage Current	$V_{IN} \geq 5\text{ mV}$, $V_{OUT} = 35\text{V}$ $T_A = 25^\circ\text{C}$		0.2	2	μA
Input Offset Voltage (Note 4)	$R_S \leq 5\text{k}$			7	mV
Input Offset Current (Note 4)				100	nA
Input Bias Current				1000	nA
Input Voltage Range	$V_S = \pm 15\text{V}$ $V^+ = 5\text{V}$, $V^- = 0$	–12 1	±13	+12 3	V V
Saturation Voltage	$V^+ \geq 4.5\text{V}$, $V^- = 0$ $V_{IN} \leq -6\text{ mV}$, $I_{SINK} \leq 3.2\text{ mA}$ $T_A \geq 0^\circ\text{C}$ $T_A \leq 0^\circ\text{C}$		0.23	0.4 0.6	V V
Output Leakage Current	$V_{IN} \geq 5\text{ mV}$, $V_{OUT} = 35\text{V}$, $V^- = V_{GND} = 0\text{V}$		1	10	μA
Differential Input Voltage				±5	V
Positive Supply Current	$T_A = 25^\circ\text{C}$, $V^+ = 5\text{V}$, $V^- = 0$		4.3		mA
Positive Supply Current	$T_A = 25^\circ\text{C}$, $V_S = \pm 15\text{V}$		8	11.5	mA
Negative Supply Current	$T_A = 25^\circ\text{C}$, $V_S = \pm 15\text{V}$		3	4.5	mA

Note 1: For supply voltages less than ±15V the absolute maximum input voltage is equal to the supply voltage.

Note 2: The maximum junction temperature of the LM119 is 150°C, while that of the LM219 is 110°C. For operating at elevated temperatures, devices in the TO-5 package must be derated based on a thermal resistance of 150°C/W, junction to ambient, or 45°C/W, junction to case. The thermal resistance of the dual-in-line package is 100°C/W, junction to ambient.

Note 3: These specifications apply for $V_S = \pm 15\text{V}$, and the Ground pin at ground, and $-55^\circ\text{C} \leq T_A \leq +125^\circ\text{C}$, unless otherwise stated. With the LM219, however, all temperature specifications are limited to $-25^\circ\text{C} \leq T_A \leq +85^\circ\text{C}$. The offset voltage, offset current and bias current specifications apply for any supply voltage from a single 5V supply up to ±15V supplies. Do not operate the device with more than 16V from ground to V_S .

Note 4: The offset voltages and offset currents given are the maximum values required to drive the output within a volt of either supply with a 1 mA load. Thus, these parameters define an error band and take into account the worst case effects of voltage gain and input impedance.

Note 5: The response time specified (see definitions) is for a 100 mV input step with 5 mV overdrive.

Note 6: Output is pulled up to 15V through a 1.4 k Ω resistor.

Note 7: Refer to RETS119X for LM119H/883, LM119H-MIL, LM119J/883 and LM119J-MIL specifications.

Absolute Maximum Ratings LM319

If Military/Aerospace specified devices are required, contact the National Semiconductor Sales Office/Distributors for availability and specifications.

Low Power Low Offset Voltage Quad Comparators

General Description

The LM139 series consists of four independent precision voltage comparators with an offset voltage specification as low as 2 mV max for all four comparators. These were designed specifically to operate from a single power supply over a wide range of voltages. Operation from split power supplies is also possible and the low power supply current drain is independent of the magnitude of the power supply voltage. These comparators also have a unique characteristic in that the input common-mode voltage range includes ground, even though operated from a single power supply voltage.

Application areas include limit comparators, simple analog to digital converters; pulse, squarewave and time delay generators; wide range VCO; MOS clock timers; multivibrators and high voltage digital logic gates. The LM139 series was designed to directly interface with TTL and CMOS. When operated from both plus and minus power supplies, they will directly interface with MOS logic— where the low power drain of the LM339 is a distinct advantage over standard comparators.

Advantages

- High precision comparators
- Reduced V_{OS} drift over temperature

- Eliminates need for dual supplies
- Allows sensing near GND
- Compatible with all forms of logic
- Power drain suitable for battery operation

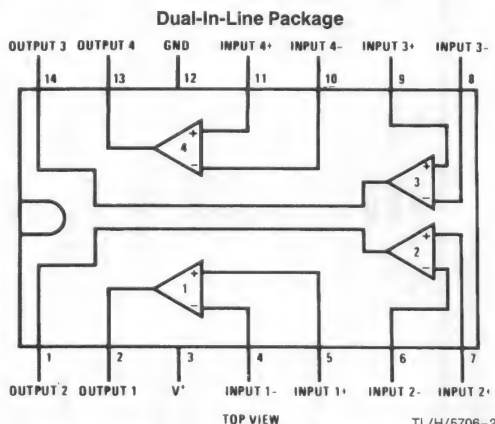

Features

- Wide single supply voltage range of dual supplies
 - LM139 series, $2 V_{DC}$ to $36 V_{DC}$ or $\pm 1 V_{DC}$ to $\pm 18 V_{DC}$
 - LM139A series, LM2901 $2 V_{DC}$ to $28 V_{DC}$ or $\pm 1 V_{DC}$ to $\pm 14 V_{DC}$
 - LM3302
- Very low supply current drain (0.8 mA) — independent of supply voltage (2 mW/comparator at $+5 V_{DC}$)
- Low input biasing current ± 5 nA
- Low input offset current ± 5 nA and offset voltage ± 3 mV
- Input common-mode voltage range includes GND
- Differential input voltage range equal to the power supply voltage
- Low output saturation voltage 250 mV at 4 mA
- Output voltage compatible with TTL, DTL, ECL, MOS and CMOS logic systems

Output Leakage Current	$V_{IN(+)} = 1 V_{DC}$, $V_{IN(-)} = 0$, $V_O = 30 V_{DC}$ (LM3302, $V_O = 28 V_{DC}$)	1.0			1.0			1.0		1.0		1.0		μA_{DC}
Differential Input Voltage	Keep all V_{IN} 's $\geq 0 V_{DC}$ (or V^- , if used), (Note 8)	36			36			36		36		28		V _{DC}

Note 1: For operating at high temperatures, the LM339/LM339A, LM2901, LM3302 must be derated based on a 125°C maximum junction temperature and a thermal resistance of 95°C/W which applies for the device soldered in a printed circuit board, operating in a still air ambient. The LM239 and LM139 must be derated based on a 150°C maximum junction temperature. The low bias dissipation and the "ON-OFF" characteristic of the outputs keeps the chip dissipation very small ($P_D \leq 100 \text{ mW}$), provided the output transistors are allowed to saturate.

Note 2: Short circuits from the output to V^+ can cause excessive heating and eventual destruction. When considering short circuits to ground, the maximum output current is approximately 20 mA independent of the magnitude of V^+ .

Note 3: This input current will only exist when the voltage at any of the input leads is driven negative. It is due to the collector-base junction of the input PNP transistors becoming forward biased and thereby acting as input diode clamps. In addition to this diode action, there is also lateral NPN parasitic transistor action on the IC chip. This transistor action can cause the output voltages of the comparators to go to the V^+ voltage level (or to ground for a large overdrive) for the time duration that an input is driven negative. This is not destructive and normal output states will re-establish when the input voltage, which was negative, again returns to a value greater than $-0.3 V_{DC}$ (at 25°C).

Note 4: These specifications are limited to $-55^\circ C \leq T_A \leq +125^\circ C$ for the LM139/LM139A. With the LM239/LM239A, all temperature specifications are limited to $-25^\circ C \leq T_A \leq +85^\circ C$, the LM339/LM339A temperature specifications are limited to $0^\circ C \leq T_A \leq +70^\circ C$, and the LM2901, LM3302 temperature range is $-40^\circ C \leq T_A \leq +85^\circ C$.

Note 5: The direction of the input current is out of the IC due to the PNP input stage. This current is essentially constant, independent of the state of the output so no loading change exists on the reference or input lines.

Note 6: The input common-mode voltage or either input signal voltage should not be allowed to go negative by more than 0.3V. The upper end of the common-mode voltage range is $V^+ - 1.5V$ at 25°C, but either or both inputs can go to $+30 V_{DC}$ without damage (25V for LM3302), independent of the magnitude of V^+ .

Note 7: The response time specified is a 100 mV input step with 5 mV overdrive. For larger overdrive signals 300 ns can be obtained, see typical performance characteristics section.

Note 8: Positive excursions of input voltage may exceed the power supply level. As long as the other voltage remains within the common-mode range, the comparator will provide a proper output state. The low input voltage state must not be less than $-0.3 V_{DC}$ (or 0.3 Vdc below the magnitude of the negative power supply, if used) (at 25°C).

Note 9: At output switch point, $V_O \approx 1.4 V_{DC}$, $R_S = 0\Omega$ with V^+ from 5 V_{DC} to 30 V_{DC}; and over the full input common-mode range (0 V_{DC} to $V^+ - 1.5 V_{DC}$), at 25°C. For LM3302, V^+ from 5 V_{DC} to 28 V_{DC}.

Note 10: Refer to RETS139AX for LM139AJ military specifications and to RETS139X for LM139J military specifications.

Application Hints

The LM139 series are high gain, wide bandwidth devices which, like most comparators, can easily oscillate if the output lead is inadvertently allowed to capacitively couple to the inputs via stray capacitance. This shows up only during the output voltage transition intervals as the comparator changes states. Power supply bypassing is not required to solve this problem. Standard PC board layout is helpful as it reduces stray input-output coupling. Reducing this input resistors to $< 10\text{ k}\Omega$ reduces the feedback signal levels and finally, adding even a small amount (1 to 10 mV) of positive feedback (hysteresis) causes such a rapid transition that oscillations due to stray feedback are not possible. Simply socketing the IC and attaching resistors to the pins will cause input-output oscillations during the small transition intervals unless hysteresis is used. If the input signal is a pulse waveform, with relatively fast rise and fall times, hysteresis is not required.

All pins of any unused comparators should be grounded.

The bias network of the LM139 series establishes a drain current which is independent of the magnitude of the power supply voltage over the range of from 2 V_{DC} to 30 V_{DC} .

It is usually unnecessary to use a bypass capacitor across the power supply line.

The differential input voltage may be larger than V^+ without damaging the device. Protection should be provided to prevent the input voltages from going negative more than $-0.3\text{ V}_{\text{DC}}$ (at 25°C). An input clamp diode can be used as shown in the applications section.

The output of the LM139 series is the uncommitted collector of a grounded-emitter NPN output transistor. Many collectors can be tied together to provide an output OR'ing function. An output pull-up resistor can be connected to any available power supply voltage within the permitted supply voltage range and there is no restriction on this voltage due to the magnitude of the voltage which is applied to the V^+ terminal of the LM139A package. The output can also be used as a simple SPST switch to ground (when a pull-up resistor is not used). The amount of current which the output device can sink is limited by the drive available (which is independent of V^+) and the β of this device. When the maximum current limit is reached (approximately 16 mA), the output transistor will come out of saturation and the output voltage will rise very rapidly. The output saturation voltage is limited by the approximately $60\Omega\text{ R}_{\text{SAT}}$ of the output transistor. The low offset voltage of the output transistor (1 mV) allows the output to clamp essentially to ground level for small load currents.

LM160/LM260/LM360 High Speed Differential Comparator

General Description

The LM160/LM260/LM360 is a very high speed differential input, complementary TTL output voltage comparator with improved characteristics over the $\mu\text{A}760/\mu\text{A}760\text{C}$, for which it is a pin-for-pin replacement. The device has been optimized for greater speed, input impedance and fan-out, and lower input offset voltage. Typically delay varies only 3 ns for overdrive variations of 5 mV to 400 mV.

Complementary outputs having minimum skew are provided. Applications involve high speed analog to digital converters and zero-crossing detectors in disk file systems.

Features

- Guaranteed high speed
- Tight delay matching on both outputs
- Complementary TTL outputs
- High input impedance
- Low speed variation with overdrive variation
- Fan-out of 4
- Low input offset voltage
- Series 74 TTL compatible

20 ns max

LM161/LM261/LM361

High Speed Differential Comparators

General Description

The LM161/LM261/LM361 is a very high speed differential input, complementary TTL output voltage comparator with improved characteristics over the SE529/NE529 for which it is a pin-for-pin replacement. The device has been optimized for greater speed performance and lower input offset voltage. Typically delay varies only 3 ns for over-drive variations of 5 mV to 500 mV. It may be operated from op amp supplies ($\pm 15V$).

Complementary outputs having maximum skew are provided. Applications involve high speed analog to digital converters and zero-crossing detectors in disk file systems.

Features

- Independent strobes
- Guaranteed high speed 20 ns max
- Tight delay matching on both outputs
- Complementary TTL outputs
- Operates from op amp supplies $\pm 15V$
- Low speed variation with overdrive variation
- Low input offset voltage
- Versatile supply voltage range

LM193/LM293/LM393, LM193A/LM293A/LM393A, LM2903 Low Power Low Offset Voltage Dual Comparators

General Description

The LM193 series consists of two independent precision voltage comparators with an offset voltage specification as low as 2.0 mV max for two comparators which were designed specifically to operate from a single power supply over a wide range of voltages. Operation from split power supplies is also possible and the low power supply current drain is independent of the magnitude of the power supply voltage. These comparators also have a unique characteristic in that the input common-mode voltage range includes ground, even though operated from a single power supply voltage.

Application areas include limit comparators, simple analog to digital converters; pulse, squarewave and time delay generators; wide range VCO; MOS clock timers; multivibrators and high voltage digital logic gates. The LM193 series was designed to directly interface with TTL and CMOS. When operated from both plus and minus power supplies, the LM193 series will directly interface with MOS logic where their low power drain is a distinct advantage over standard comparators.

Advantages

- High precision comparators
- Reduced V_{OS} drift over temperature

- Eliminates need for dual supplies
- Allows sensing near ground
- Compatible with all forms of logic
- Power drain suitable for battery operation

Features

- Wide single supply
Voltage range $2.0 V_{DC}$ to $36 V_{DC}$
or dual supplies $\pm 1.0 V_{DC}$ to $\pm 18 V_{DC}$
- Very low supply current drain (0.8 mA) — independent of supply voltage (1.0 mW/comparator at $5.0 V_{DC}$)
- Low input biasing current $\pm 5 \text{ nA}$
- Low input offset current $\pm 5 \text{ nA}$
and maximum offset voltage $\pm 3 \text{ mV}$
- Input common-mode voltage range includes ground
- Differential input voltage range equal to the power supply voltage
- Low output saturation voltage, 250 mV at 4 mA
- Output voltage compatible with TTL, DTL, ECL, MOS and CMOS logic systems

Note 1: For operating at high temperatures, the LM393/LM393A and LM2903 must be derated based on a 125°C maximum junction temperature and a thermal resistance of $127^\circ\text{C}/\text{W}$ which applies for the device soldered in a printed circuit board, operating in a still air ambient. The LM193/LM193A/LM293/LM293A must be derated based on a 150°C maximum junction temperature. The low bias dissipation and the "ON-OFF" characteristic of the outputs keeps the chip dissipation very small ($P_D \leq 100 \text{ mW}$), provided the output transistors are allowed to saturate.

Note 2: Short circuits from the output to V^+ can cause excessive heating and eventual destruction. When considering short circuits to ground, the maximum output current is approximately 20 mA independent of the magnitude of V^+ .

Note 3: This input current will only exist when the voltage at any of the input leads is driven negative. It is due to the collector-base junction of the input PNP transistors becoming forward biased and thereby acting as input diode clamps. In addition to this diode action, there is also lateral NPN parasitic transistor action on the IC chip. This transistor action can cause the output voltages of the comparators to go to the V^+ voltage level (or to ground for a large overdrive) for the time duration that an input is driven negative. This is not destructive and normal output states will re-establish when the input voltage, which was negative, again returns to a value greater than $-0.3 V_{DC}$.

Note 4: These specifications are limited to $-55^\circ\text{C} \leq T_A \leq +125^\circ\text{C}$, for the LM193/LM193A, With the LM293/LM293A all temperature specifications are limited to $-25^\circ\text{C} \leq T_A \leq +85^\circ\text{C}$ and the LM393/LM393A temperature specifications are limited to $0^\circ\text{C} \leq T_A \leq +70^\circ\text{C}$. The LM2903 is limited to $-40^\circ\text{C} \leq T_A \leq +85^\circ\text{C}$.

Note 5: The direction of the input current is out of the IC due to the PNP input stage. This current is essentially constant, independent of the state of the output so no loading change exists on the reference or input lines.

Note 6: The input common-mode voltage or either input signal voltage should not be allowed to go negative by more than $0.3V$. The upper end of the common-mode voltage range is $V^+ - 1.5V$ at 25°C , but either or both inputs can go to $30 V_{DC}$ without damage, independent of the magnitude of V^+ .

Note 7: The response time specified is for a 100 mV input step with 5 mV overdrive. For larger overdrive signals 300 ns can be obtained, see typical performance characteristics section.

Note 8: Positive excursions of input voltage may exceed the power supply level. As long as the other voltage remains within the common-mode range, the comparator will provide a proper output state. The low input voltage state must not be less than $-0.3 V_{DC}$ (or $0.3 V_{DC}$ below the magnitude of the negative power supply, if used).

Note 9: At output switch point, $V_O \approx 1.4 V_{DC}$, $R_S = 0\Omega$ with V^+ from $5 V_{DC}$ to $30 V_{DC}$; and over the full input common-mode range ($0 V_{DC}$ to $V^+ - 1.5 V_{DC}$) at 25°C .

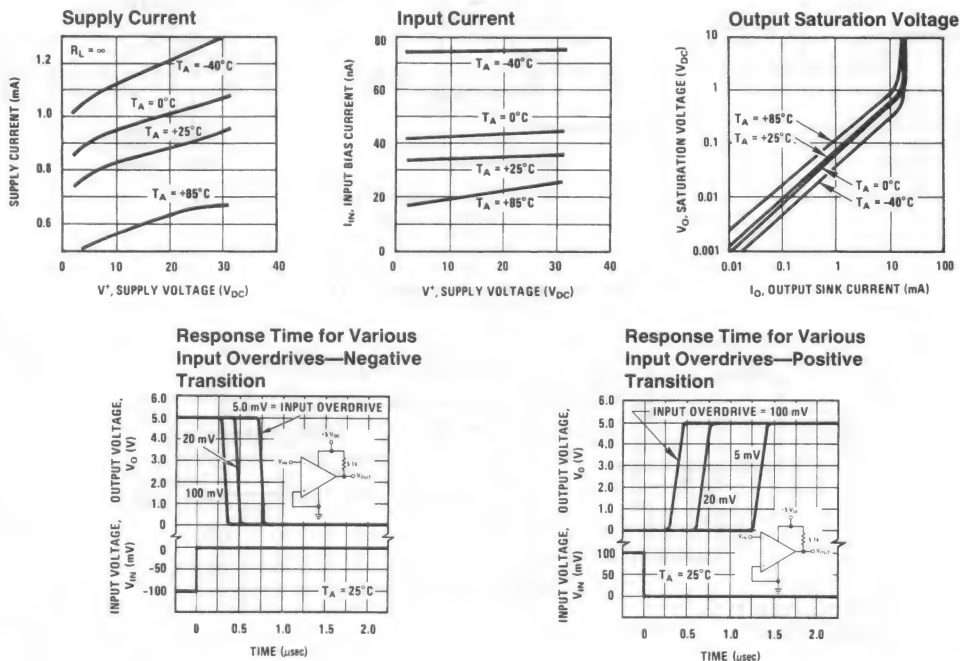

Note 10: Refer to RETS193AX for LM193AH/military specifications and to RETS193X for LM193H/military specifications.

Typical Performance Characteristics LM2903

TL/H/5709-4

Application Hints

The LM193 series are high gain, wide bandwidth devices which, like most comparators, can easily oscillate if the output lead is inadvertently allowed to capacitively couple to the inputs via stray capacitance. This shows up only during the output voltage transition intervals as the comparator change states. Power supply bypassing is not required to solve this problem. Standard PC board layout is helpful as it reduces stray input-output coupling. Reducing the input resistors to $< 10\text{ k}\Omega$ reduces the feedback signal levels and finally, adding even a small amount (1.0 to 10 mV) of positive feedback (hysteresis) causes such a rapid transition that oscillations due to stray feedback are not possible. Simply socketing the IC and attaching resistors to the pins will cause input-output oscillations during the small transition intervals unless hysteresis is used. If the input signal is a pulse waveform, with relatively fast rise and fall times, hysteresis is not required.

All pins of any unused comparators should be grounded.

The bias network of the LM193 series establishes a drain current which is independent of the magnitude of the power supply voltage over the range of from 2.0 V_{DC} to 30 V_{DC} .

It is usually unnecessary to use a bypass capacitor across the power supply line.

The differential input voltage may be larger than V^+ without damaging the device (see Note 8). Protection should be provided to prevent the input voltages from going negative more than $-0.3\text{ V}_{\text{DC}}$ (at 25°C). An input clamp diode can be used as shown in the applications section.

The output of the LM193 series is the uncommitted collector of a grounded-emitter NPN output transistor. Many collectors can be tied together to provide an output OR'ing function. An output pull-up resistor can be connected to any available power supply voltage within the permitted supply voltage range and there is no restriction on this voltage due to the magnitude of the voltage which is applied to the V^+ terminal of the LM193 package. The output can also be used as a simple SPST switch to ground (when a pull-up resistor is not used). The amount of current which the output device can sink is limited by the drive available (which is independent of V^+) and the β of this device. When the maximum current limit is reached (approximately 16 mA), the output transistor will come out of saturation and the output voltage will rise very rapidly. The output saturation voltage is limited by the approximately $60\Omega\text{ }r_{\text{SAT}}$ of the output transistor. The low offset voltage of the output transistor (1.0 mV) allows the output to clamp essentially to ground level for small load currents.

LP265/LP365 Micropower Programmable Quad Comparator

General Description

The LP365 consists of four independent voltage comparators. The comparators can be programmed, four at the same time, for various supply currents, input currents, response times and output current drives. This is accomplished by connecting a single resistor between the V_{CC} and I_{SET} pins.

These comparators can be operated from split power supplies or from a single power supply over a wide range of voltages. The input can sense signals at ground level even with single supply operation. The unique output NPN transistor stages are uncommitted to either power supply. They can be connected directly to various logic system supplies so that they are highly flexible to interface with various logic families.

Application areas include battery power circuits, threshold detectors, zero crossing detectors, simple serial A/D converters, VCO, multivibrators, voltage converters, power sequencers, and high performance V/F converters, and RTD linearization.

Features

- Single programming resistor to tailor power consumption, input current, speed and output current drive capability
- Wide single supply voltage range or dual supplies (4 V_{DC} to 36 V_{DC} or $\pm 2.0 V_{DC}$ to $\pm 18 V_{DC}$)
- Low supply current drain (10 μA) and low power consumption (10 μW /comparator) @ $I_{SET} = 0.5 \mu A$ $V_{CC} = 5V_{DC}$
- Uncommitted output stage—selectable output levels
- Output directly compatible with DTL, TTL, CMOS, MOS or other special logic families
- Input common-mode range includes ground
- Differential input voltage equal to the power supply voltage

Typical Connection

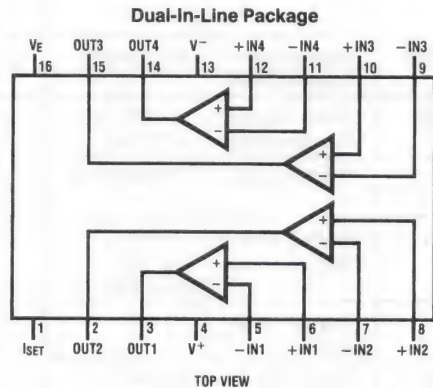

TL/H/5023-1

Programming Equation

$$I_{SET} = \frac{(V^+) - (V^-) - 1.3V}{R_{SET}}$$

$$I_{SUPPLY} \approx 22 \times I_{SET}$$

t_R	Response Time	$V_{CC} = 5V$, $V_E = 0V$, $R_L = 5k$, $C_L = 10 pF$ (Note 7)	1.0			1.0			μs

Note 1: The input voltage is not allowed to go 0.3V above V^+ or -0.3V below V^- as this will turn on a parasitic transistor causing large currents to flow through the device.

Note 2: Short circuits from the output to V^+ may cause excessive heating and eventual destruction. The current in the output leads and the V_E lead should not be allowed to exceed 30 mA. The output should not be shorted to V^- if $V_E \leq (V^-) + 7V$.

Note 3: For operating at elevated temperatures, these devices must be derated based on a thermal resistance of θ_{JA} and T_J max. $T_J = T_A + \theta_{JA}P_D$.

Note 4: Boldface numbers apply at temperature extremes. All other numbers apply at $T_A = T_J = 25^\circ C$. $V^+ = 5V$, $V^- = 0V$, $I_{SET} = 10 \mu A$, $R_L = 100k$, and $V_C = 5V$ as shown in the Typical Connection diagram.

Note 5: Guaranteed and 100% production tested.

Note 6: Guaranteed (but not 100% production tested) over the operating temperature and supply voltage ranges. These limits are not used to calculate out-going quality levels.

Note 7: The response time specified is for a 100 mV input step with 5 mV overdrive.

Note 8: Boldface numbers apply at temperature extremes. All other numbers apply at $T_A = T_J = 25^\circ C$. $V^+ = +15V$, $V^- = -15V$, $I_{SET} = 100 \mu A$, $R_L = 100k$, and $V_C = 5V$ as shown in the Typical Connection diagram.

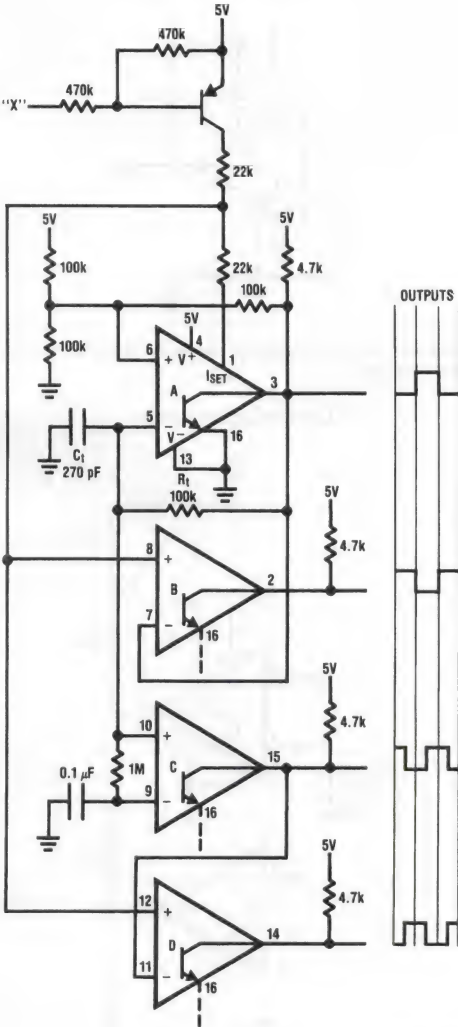

Note 9: See AN-450 "Surface Mounting Methods and Their Effect on Product Reliability" (Appendix D) for other methods of soldering surface mount devices.

Typical Performance Characteristics

Typical Applications

Gated 4-Phase Oscillator

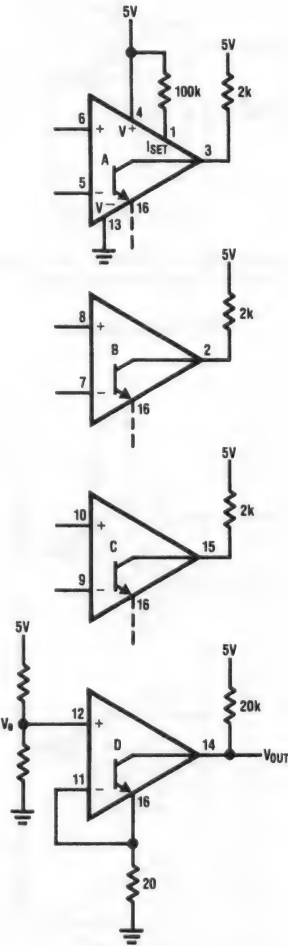

TL/H/5023-4

$$f = 20 \text{ kHz}$$

$$f = \frac{1}{1.6 \cdot R_1 \cdot C_1}$$

All four phases run when X is low. When X is high, oscillation stops and power drain is zero.

Voltage Comparator

TL/H/5023-5

If you choose $V_e = 25 \text{ mV}$, 75 mV , or 125 mV , then V_{OUT} will fall if $\frac{1}{3}$, $\frac{2}{3}$ or all of the other three outputs are low.

Typical Applications (Continued)

Ordinary Hysteresis

TL/H/5023-6

It is a good practice to add a few millivolts of positive feedback to prevent oscillation when the input voltage is near the threshold.

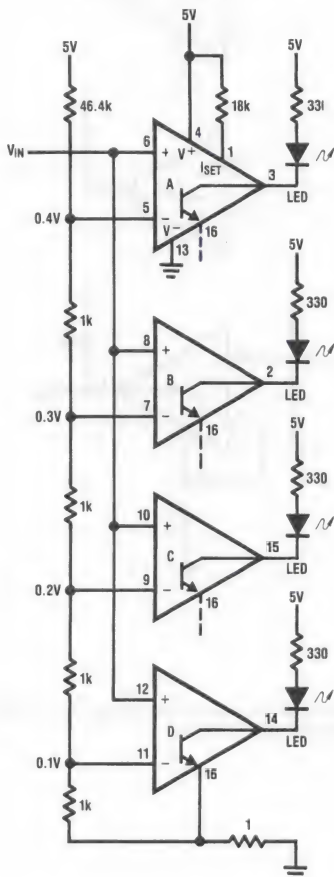

Hysteresis from Emitter

TL/H/5023-7

Positive feedback from the emitter can also prevent oscillations when V_{IN} is near the threshold.

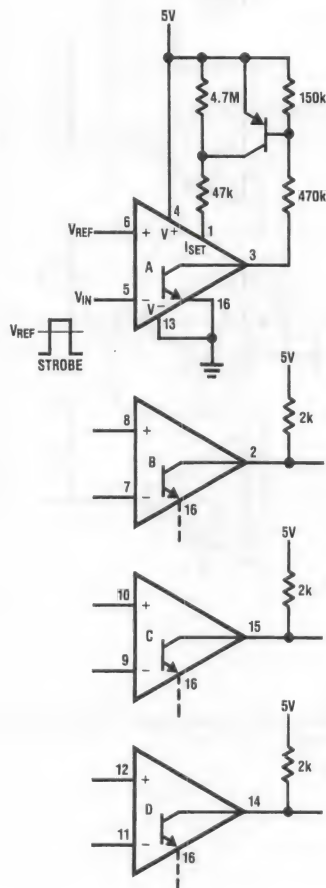

Bar-Graph Display

TL/H/5023-8

The positive feedback from pin 16 provides hysteresis.

Level-Sensitive Strobe

TL/H/5023-9

Comparators B, C, and D do not respond until activated by the signal applied to comparator A.

Typical Applications (Continued)

Slow Op Amp (Inverter)

TL/H/5023-10

$$R_B = V^+ / 20 \mu A$$

Unlike most comparators, the LP365 can be used as an op amp, if suitable R-C damping networks are used.

Slow Op Amp (Unity-Gain Follower)

TL/H/5023-11

$$R_B = V^+ / 20 \mu A$$

The LP365 can also be used as a high-input-impedance follower-amplifier with the damping components shown.

Chopping Outputs

TL/H/5023-12

Chopping the outputs by modulating the I_{SET} current allows data to be transmitted via opto-couplers, transformers, etc.

Low Battery Detector

TL/H/5023-13

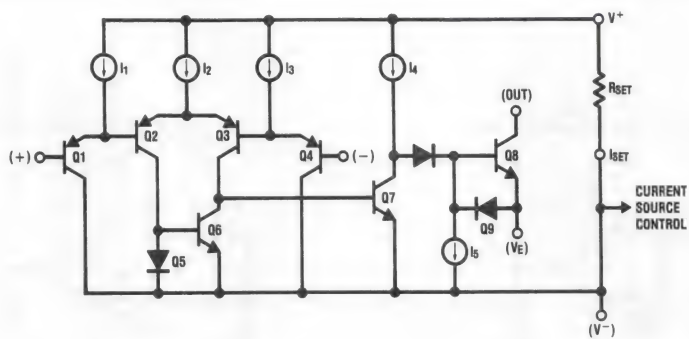

$$I_S @ 6V = 45 \mu A$$

$$I_S @ 3.8V = 1 \mu A$$

$f = 3 \text{ kHz}$

Comparator A detects when the supply voltage drops to 4V and enables comparator B to drive a piezoelectric alarm.

Simplified Schematic

TL/H/5023-14

Current sources are programmed by I_{SET}

V_E is common to all 4 comparators

LP311 Voltage Comparator

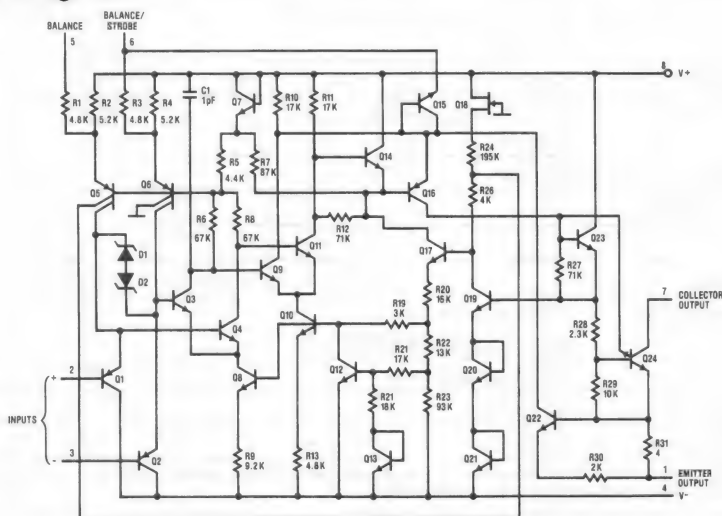

General Description

The LP311 is a low power version of the industry-standard LM311. It takes advantage of stable high-value ion-implanted resistors to perform the same function as an LM311, with a 30:1 reduction in power drain, but only a 6:1 slowdown of response time. Thus the LP311 is well suited for battery-powered applications, and all other applications where fast response is not needed. It operates over a wide range of supply voltages from 36V down to a single 3V supply, with less than 200 μ A drain, but it is still capable of driving a 25 mA load. The LP311 is quite easy to apply without any oscillation, if ordinary precautions are taken to minimize stray coupling from the output to either input or to the trim pins. (See the LM311 section of the Linear Databook.)

Features

- Low power drain, 900 μ W on 5V supply
- Operates from ± 15 V or a single supply as low as 3V
- Output can drive 25 mA
- Emitter output can swing below negative supply
- Response time: 1.2 μ s
- Same pin-out as LM311
- Low input currents: 2 nA of offset, 15 nA of bias
- Large common-mode input range: -14.6 V to 13.6 V with ± 15 V supply

Schematic Diagram

Voltage Gain	$T_A = 25^\circ\text{C}$, $R_L = 5k$	40	200		V/mV
Response Time (Note 5)	$T_A = 25^\circ\text{C}$		1.2		μs
Saturation Voltage (Note 6)	$V_{IN} \leq -10\text{ mV}$, $I_{OUT} = 25\text{ mA}$ $T_A = 25^\circ\text{C}$		0.4	1.5	V
Strobe Current (Note 7)	$T_A = 25^\circ\text{C}$	100	200	300	μA
Output Leakage Current	$V_{IN} \geq 10\text{ mV}$, $V_{OUT} = 35V$ $T_A = 25^\circ\text{C}$		0.2	100	nA
Input Offset Voltage (Note 4)	$R_S \leq 100k$			10	mV
Input Offset Current (Note 4)				35	nA
Input Bias Current				150	nA
Input Voltage Range		$V^- + 0.5$	$+13.7, -14.7$	$V^+ - 1.5$	V
Saturation Voltage (Note 6)	$V^+ \geq 4.5V$, $V^- = 0V$ $V_{IN} \leq -10\text{ mV}$, $I_{SINK} \leq 1.6\text{ mA}$		0.1	0.4	V
Positive Supply Current	$T_A = 25^\circ\text{C}$, Output on		150	300	μA
Negative Supply Current	$T_A = 25^\circ\text{C}$		80	180	μA
Minimum Operating Voltage	$T_A = 25^\circ\text{C}$		3.0	3.5	V

Note 1: This rating applies for $\pm 15V$ supplies. The positive input voltage limit is 30V above the negative supply. The negative input voltage limit is equal to the negative supply voltage or 30V below the positive supply, whichever is less.

Note 2: The maximum junction temperature of the LP311 is 85°C. For operating at elevated temperatures, devices in the dual-in-line package must be derated based on a thermal resistance of 160°C/W, junction to ambient.

Note 3: These specifications apply for $V_S = \pm 15V$ and $0^\circ\text{C} \leq T_A \leq 70^\circ\text{C}$, unless otherwise specified. The offset voltage, offset current and bias current specifications apply for any supply voltage from a single 4V supply up to $\pm 15V$ supplies.

Note 4: The offset voltages and offset currents given are the maximum values required to drive the output within a volt of either supply with 1 mA load. Thus, these parameters define an error band and take into account the worst-case effects of voltage gain and input impedance.

Note 5: The response time specified is for a 100 mV input step with 5 mV overdrive.

Note 6: Saturation voltage specification applied to collector-emitter voltage (V_{7-1}) for $V_{COLLECTOR} \leq (V^+ - 3V)$.

Note 7: Do not short the strobe pin to ground. It should be current driven, 100 μA to 300 μA .

LP339 Ultra-Low Power Quad Comparator

General Description

The LP339 consists of four independent voltage comparators designed specifically to operate from a single power supply and draw typically 60 μA of power supply drain current over a wide range of power supply voltages. Operation from split supplies is also possible and the ultra-low power supply drain current is independent of the power supply voltage. These comparators also feature a common-mode range which includes ground, even when operated from a single supply.

Applications include limit comparators, simple analog-to-digital converters, pulse, square and time delay generators; VCO's; multivibrators; high voltage logic gates. The LP339 was specifically designed to interface with the CMOS logic family. The ultra-low supply current makes the LP339 valuable in battery powered applications.

Advantages

- Ultra-low power supply drain suitable for battery applications

- Single supply operation
- Sensing at ground
- Compatible with CMOS logic family
- Pin-out identical to LM339

Features

- Ultra-low power supply current drain (60 μA)—independent of the supply voltage (75 μW /comparator at $+5\text{ V}_{\text{DC}}$)
- Low input biasing current 3 nA
- Low input offset current $\pm 0.5\text{ nA}$
- Low input offset voltage $\pm 2\text{ mV}$
- Input common-mode voltage includes ground
- Output voltage compatible with MOS and CMOS logic
- High output sink current capability (30 mA at $V_{\text{O}} = 2\text{ V}_{\text{DC}}$)
- Supply Input protected against reverse voltages

Differential Input Voltage	All V _{IN} 's ≥ 0 V _{DC} (or V ₋ on split supplies) (Note 8)			36	V _{DC}

Note 1: For elevated temperature operation, T_J max is 125°C for the LP339. θ_{JA} (junction to ambient) is 175°C/W for the LP339N and 120°C/W for the LP339M when either device is soldered in a printed circuit board in a still air environment. The low bias dissipation and the "ON-OFF" characteristic of the outputs keeps the chip dissipation very small (P_D ≤ 100 mW), provided the output transistors are allowed to saturate.

Note 2: Short circuits from the output to V₊ can cause excessive heating and eventual destruction. The maximum output current is approximately 50 mA.

Note 3: This input current will only exist when the voltage at any of the input leads is driven negative. It is due to the collector-base junction of the input PNP transistors becoming forward biased and thereby acting as input clamp diodes. In addition to this diode action, there is also lateral NPN parasitic transistor action on the IC chip. This transistor action can cause the output voltage of the comparators to go to the V₊ voltage level (or to ground for a large input overdrive) for the time duration that an input is driven negative. This is not destructive and normal output states will re-establish when the input voltage, which is negative, again returns to a value greater than -0.3 V_{DC} (T_A = 25°C).

Note 4: These specifications apply for V₊ = 5V_{DC} and 0°C ≤ T_A ≤ 70° C, unless otherwise stated. The temperature extremes are guaranteed but not 100% production tested. These parameters are not used to calculate outgoing AQL.

Note 5: The direction of the input current is out of the IC due to the PNP input stage. This current is essentially constant, independent of the state of the output, so no loading change exists on the reference or the input lines as long as the common-mode range is not exceeded.

Note 6: The input common-mode voltage or either input voltage should not be allowed to go negative by more than 0.3V. The upper end of the common-mode voltage range is V₊ - 1.5V (T_A = 25°C), but either or both inputs can go to 30 V_{DC} without damage.

Note 7: The response time specified is for a 100 mV input step with 5 mV overdrive. For larger overdrive signals 1.3 μs can be obtained. See Typical Performance Characteristics section.

Electrical Characteristics ($V^+ = 5\text{ V}_{\text{DC}}$, Note 4) (Continued)

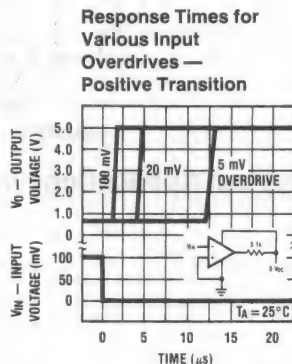

Note 8: Positive excursions of input voltage may exceed the power supply level. As long as the other voltage remains within the common-mode range, the comparator will provide a proper output state. The low input voltage state must not be less than $-0.3\text{ V}_{\text{DC}}$ (or 0.3 V_{DC} below the magnitude of the negative power supply, if used) at $T_A = 25^\circ\text{C}$.

Note 9: At output switch point, $V_O = 1.4\text{ V}$, $R_S = 0\Omega$ with V^+ from 5 V_{DC} ; and over the full input common-mode range (0 V_{DC} to $V^+ - 1.5\text{ V}_{\text{DC}}$).

Note 10: For input signals that exceed V^+ , only the overdriven comparator is affected. With a 5 V supply, V_{IN} should be limited to 25 V maximum, and a limiting resistor should be used on all inputs that might exceed the positive supply.

Note 11: The output sink current is a function of the output voltage. The LP339 has a bi-modal output section which allows it to sink large currents via a Darlington connection at output voltages greater than approximately 1.5 V_{DC} and sink lower currents below this point. (See typical characteristics section and applications section).

Typical Performance Characteristics

TL/H/5226-10

Application Hints

All pins of any unused comparators should be grounded.

The bias network of the LP339 establishes a drain current which is independent of the magnitude of the power supply voltage over the range of from $2 V_{DC}$ to $30 V_{DC}$.

It is usually unnecessary to use a bypass capacitor across the power supply line.

The differential input voltage may be larger than $V+$ without damaging the device. Protection should be provided to prevent the input voltages from going negative more than $-0.3 V_{DC}$ (at 25°C). An input clamp diode can be used as shown in the application section.

The output section of the LP339 has two distinct modes of operation—a Darlington mode and a grounded emitter mode. This unique drive circuit permits the LP339 to sink 30 mA at $V_O = 2 V_{DC}$ (Darlington mode) and $700 \mu\text{A}$ at $V_O = 0.4 V_{DC}$ (grounded emitter mode). Figure 1 is a simplified schematic diagram of the LP339 output section.

FIGURE 1

TL/H/5226-11

Notice that the output section is configured in a Darlington connection (ignoring Q3). Therefore, if the output voltage is held high enough ($V_O \geq 1 V_{DC}$), Q1 is not saturated and the output current is limited only by the product of the betas of Q1, Q2 and I1 (and the $60 \Omega R_{SAT}$ of Q2). The LP339 is thus capable of driving LED's, relays, etc. in this mode while maintaining an ultra-low power supply current of typically $60 \mu\text{A}$.

If transistor Q3 were omitted, and the output voltage allowed to drop below about $0.8 V_{DC}$, transistor Q1 would saturate and the output current would drop to zero. The circuit would, therefore, be unable to 'pull' low current loads down to ground (or the negative supply, if used). Transistor Q3 has been included to bypass transistor Q1 under these conditions and apply the current I1 directly to the base of Q2. The output sink current is now approximately I1 times the beta of Q2 ($700 \mu\text{A}$ at $V_O = 0.4 V_{DC}$). The output of the LP339 exhibits a bi-modal characteristic with a smooth transition between modes. (See Output Sink Current graphs in Typical Performance Characteristics section.)

It is also important to note that in both cases the output is an uncommitted collector. Therefore, many collectors can be tied together to provide an output OR'ing function. An output pull-up resistor can be connected to any available power supply voltage within the permitted power supply voltage range and there is no restriction on this voltage due to the magnitude of the voltage which is applied to the $V+$ terminal of the LP339 package.

Instrumentation Amplifiers Definition of Terms

Bandwidth: That frequency at which the voltage gain is reduced to $1/\sqrt{2}$ times the low frequency value.

Common-Mode Rejection Ratio: The ratio of the input common-mode voltage range to the peak-to-peak change in input offset voltage over this range.

Harmonic Distortion: That percentage of harmonic distortion being defined as one-hundred times the ratio of the root-mean-square (rms) sum of the harmonics to the fundamental. % harmonic distortion =

$$\frac{(V_2^2 + V_3^2 + V_4^2 + \dots)^{1/2}}{V_1} (100\%)$$

where V_1 is the rms amplitude of the fundamental and V_2, V_3, V_4, \dots are the rms amplitudes of the individual harmonics.

Input Bias Current: The average of the two input currents.

Input Common-Mode Voltage Range: The range of voltages on the input terminals for which the amplifier is operational. Note that the specifications are not guaranteed over the full common-mode voltage range unless specifically stated.

Input Impedance: The ratio of input voltage to input current under the stated conditions for source resistance (R_S) and load resistance (R_L).

Input Offset Current: The difference in the currents into the two input terminals when the output is at zero.

Input Offset Voltage: That voltage which must be applied between the input terminals through two equal resistances to obtain zero output voltage.

Input Resistance: The ratio of the change in input voltage to the change in input current on either input with the other grounded.

Input Voltage Range: The range of voltages on the input terminals for which the amplifier operates within specifications.

Large-Signal Voltage Gain: The ratio of the output voltage swing to the change in input voltage required to drive the output from zero to this voltage.

Output Impedance: The ratio of output voltage to output current under the stated conditions for source resistance (R_S) and load resistance (R_L).

Output Resistance: The small signal resistance seen at the output with the output voltage near zero.

Output Voltage Swing: The peak output voltage swing, referred to zero, that can be obtained without clipping.

Offset Voltage Temperature Drift: The average drift rate of offset voltage for a thermal variation from room temperature to the indicated temperature extreme.

Power Supply Rejection: The ratio of the change in input offset voltage to the change in power supply voltages producing it.

Settling Time: The time between the initiation of the input step function and the time when the output voltage has settled to within a specified error band of the final output voltage.

Slew Rate: The internally-limited rate of change in output voltage with a large-amplitude step function applied to the input.

Supply Current: The current required from the power supply to operate the amplifier with no load and the output midway between the supplies.

Transient Response: The closed-loop step-function response of the amplifier under small-signal conditions.

Unity Gain Bandwidth: The frequency range from dc to the frequency where the amplifier open loop gain rolls off to one.

Voltage Gain: The ratio of output voltage to input voltage under the stated conditions for source resistance (R_S) and load resistance (R_L).

LH0036/LH0036C

LH0036/LH0036C Instrumentation Amplifier

General Description

The LH0036/LH0036C is a true micro power instrumentation amplifier designed for precision differential signal processing. Extremely high accuracy can be obtained due to the 300 M Ω input impedance and excellent 100 dB common mode rejection ratio. It is packaged in a hermetic TO-8 package. Gain is programmable from 1 to 1000 with a single external resistor. Power supply operating range is between $\pm 1V$ and $\pm 18V$. Input bias current and output bandwidth are both externally adjustable or can be set by internally set values. The LH0036 is specified for operation over the $-55^{\circ}C$ to $+125^{\circ}C$ temperature range and the LH0036C is specified for operation over the $-25^{\circ}C$ to $+85^{\circ}C$ temperature range.

Features

- High input impedance
- High CMRR
- Single resistor gain adjust
- Low power
- Wide supply range
- Adjustable input bias current
- Adjustable output bandwidth
- Guard drive output

Applications Information

THEORY OF OPERATION

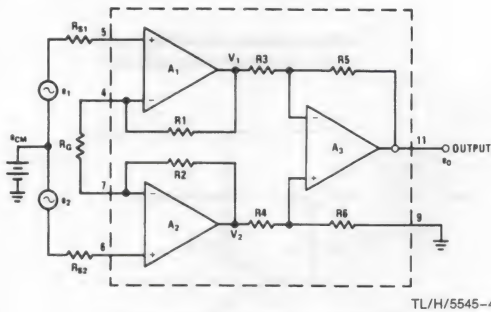

FIGURE 1. Simplified LH0036

The LH0036 is a 2 stage amplifier with a high input impedance gain stage comprised of A_1 and A_2 and a differential to single-ended unity gain stage, A_3 . Operational amplifier, A_1 , receives differential input signal, e_1 , and amplifies it by a factor equal to $(R_1 + R_G)/R_G$.

A_1 also receives input e_2 via A_2 and R_2 . e_2 is seen as an inverting signal with a gain of R_1/R_G . A_1 also receives the common mode signal e_{CM} and processes it with a gain of +1.

Hence:

$$V_1 = \frac{R_1 + R_G}{R_G} e_1 - \frac{R_1}{R_G} e_2 + e_{CM} \quad (1)$$

By similar analysis V_2 is seen to be:

$$V_2 = \frac{R_2 + R_G}{R_G} e_2 - \frac{R_2}{R_G} e_1 + e_{CM} \quad (2)$$

For $R_1 = R_2$:

$$V_2 - V_1 = \left[\left(\frac{2R_1}{R_G} \right) + 1 \right] (e_2 - e_1) \quad (3)$$

Also, for $R_3 = R_5 = R_4 = R_6$, the gain of $A_3 = 1$, and:

$$e_0 = (1)(V_2 - V_1) = (e_2 - e_1) \left[1 + \left(\frac{2R_1}{R_G} \right) \right] \quad (4)$$

As can be seen for identically matched resistors, e_{CM} is cancelled out, and the differential gain is dictated by equation (4).

For the LH0036, equation (4) reduces to:

$$A_{VCL} = \frac{e_0}{e_2 - e_1} = 1 + \frac{50k}{R_G} \quad (5a)$$

The closed loop gain may be set to any value from 1 ($R_G = \infty$) to 1000 ($R_G \approx 50\Omega$). Equation (5a) re-arranged in more convenient form may be used to select R_G for a desired gain:

$$R_G = \frac{50k}{A_{VCL} - 1} \quad (5b)$$

USE OF BANDWIDTH CONTROL (pin 1)

In the standard configuration, pin 1 of the LH0036 is simply grounded. The amplifier's slew rate in this configuration is

typically $0.3V/\mu s$ and small signal bandwidth 350 kHz for $A_{VCL} = 1$. In some applications, particularly at low frequency, it may be desirable to limit bandwidth in order to minimize the overall noise bandwidth of the device. A resistor R_{BW} may be placed between pin 1 and ground to accomplish this purpose. Figure 2 shows typical small signal bandwidth versus R_{BW} .

FIGURE 2. Bandwidth vs R_{BW}

It also should be noted that large signal bandwidth and slew rate may be adjusted down by use of R_{BW} . Figure 3 is plot of slew rate versus R_{BW} .

FIGURE 3. Output Slew Rate vs R_{BW}

CMRR CONSIDERATIONS

Use of Pin 9, CMRR Preset

Pin 9 should be grounded for nominal operation. An internal factory trimmed resistor, R_6 , will yield a CMRR in excess of 80 dB (for $A_{VCL} = 100$). Should a higher CMRR be desired, pin 9 should be left open and the procedure, in this section followed.

DC Off-set Voltage and Common Mode Rejection Adjustments

Off-set may be nulled using the circuit shown in Figure 4.

FIGURE 4. V_{OS} Adjustment Circuit

Applications Information (Continued)

Pin 8 is also used to improve the common mode rejection ratio as shown in *Figure 5*. Null is achieved by alternately applying $\pm 10V$ (for V^+ & $V^- = 15V$) to the inputs and adjusting R_1 for minimum change at the output.

TL/H/5545-8

FIGURE 5. CMRR Adjustment Circuit

The circuits of *Figure 4* and *5* may be combined as shown in *Figure 6* to accomplish both V_{OS} and CMRR null. However, the V_{OS} and CMRR adjustment are interactive and several iterations are required. The procedure for null should start with the inputs grounded.

TL/H/5545-10

FIGURE 6. Combined CMRR, V_{OS} Adjustment Circuit

R_2 is adjusted for V_{OS} null. An input of $+10V$ is then applied and R_1 is adjusted for CMRR null. The procedure is then repeated until the optimum is achieved.

A circuit which overcomes adjustment interaction is shown in *Figure 7*. In this case, R_2 is adjusted first for output null with $+10V$ input. It is always a good idea to check CMRR null with a $-10V$ input. The optimum null achievable will yield the highest CMRR over the amplifiers common mode range.

TL/H/5545-11

*Note: Nominal value R_1 to Achieve Optimum CMRR is 3.0 k Ω .

FIGURE 7. Improved V_{OS} , CMRR Nulling Circuit

AC CMRR Considerations

The ac CMRR may be improved using the circuit of *Figure 8*.

TL/H/5545-9

FIGURE 8. Improved AC CMRR Circuit

After adjusting R_1 for best dc CMRR as before, R_2 should be adjusted for minimum peak-to-peak voltage at the output while applying an ac common mode signal of the maximum amplitude and frequency of interest.

INPUT BIAS CURRENT CONTROL

Under nominal operating conditions (pin 3 grounded), the LH0036 requires input currents of 40 nA. The input current may be reduced by inserting a resistor (R_B) between 3 and ground or, alternatively, between 3 and V^- . For R_B returned to ground, the input bias current may be predicted by:

$$I_{BIAS} \cong \frac{V^+ - 0.5}{4 \times 10^8 + 800 R_B} \quad (6a)$$

or

$$R_B = \frac{V^+ - 0.5 - (4 \times 10^8) (I_{BIAS})}{800 I_{BIAS}} \quad (6b)$$

Where:

I_{BIAS} = Input Bias Current (nA)

R_B = External Resistor connected between pin 3 and ground (Ohms)

V^+ = Positive Supply Voltage (Volts)

Figure 9 is a plot of input bias current versus R_B .

TL/H/5545-12

FIGURE 9. Input Bias Current as a Function of R_B

As indicated above, R_B may be returned to the negative supply voltage. Input bias current may then be predicted by:

$$I_{BIAS} \cong \frac{(V^+ - V^-) - 0.5}{4 \times 10^8 + 800 R_B}$$

Applications Information (Continued)

or

$$R_B \approx \frac{(V^+ - V^-) - 0.5 - (4 \times 10^8)(I_{BIAS})}{800 I_{BIAS}} \quad (8)$$

Where:

I_{BIAS} = Input Bias Current (nA)

R_B = External resistor connected between pin 3 and V^- (Ohms)

V^+ = Positive Supply Voltage (Volts)

V^- = Negative Supply Voltage (Volts)

TL/H/5545-13

FIGURE 10. Input Bias Current as a Function of R_B

TL/H/5545-14

FIGURE 11. Unity Gain Bandwidth as a Function of R_B

BIAS CURRENT RETURN PATH CONSIDERATIONS

The LH0036 exhibits input bias currents typically in the 40 nA region in each input. This current must flow through R_{ISO} as shown in Figure 12.

TL/H/5545-16

FIGURE 12. Bias Current Return Path

In a typical application, $V_S = \pm 15V$, $I_{B1} \approx I_{B2} \approx 40$ nA, the total current, I_T , would flow through R_{ISO} causing a voltage rise at point A. For values of $R_{ISO} \geq 150$ MΩ, the voltage at point A exceeds the +12V common range of the device. Clearly, for $R_{ISO} = \infty$, the LH0036 would be driven to positive saturation.

The implication is that a finite impedance must be supplied between the input and power supply ground. The value of the resistor is dictated by the maximum input bias current, and the common mode voltage. Under worst case conditions:

$$R_{ISO} \leq \frac{V_{CMR} - V_{CM}}{I_T} \quad (9)$$

Where:

V_{CMR} = Common Mode Range (10V for the LH0036)

V_{CM} = Common Mode Voltage

$I_T = I_{B1} + I_{B2}$

In applications in which the signal source is floating, such as a thermocouple, one end of the source may be grounded directly or through a resistor.

GUARD OUTPUT

Pin 2 of the LH0036 is provided as a guard drive pin in those stringent applications which require very low leakage and minimum input capacitance. Pin 2 will always be biased at the input common mode voltage. The source impedance looking into pin 2 is approximately 15 kΩ. Proper use of the guard/shield pin is shown in Figure 13.

TL/H/5545-15

FIGURE 13. Use of Guard

For applications requiring a lower source impedance than 15 kΩ, a unity gain buffer, such as the LH0002 may be inserted between pin 2 and the input shields as shown in Figure 14.

TL/H/5545-17

FIGURE 14. Guard Pin With Buffer

Definition of Terms

Bandwidth: The frequency at which the voltage gain is reduced to 0.707 of the low frequency (dc) value.

Closed Loop Gain, A_{VCL} : The ratio of the output voltage swing to the input voltage swing determined by $A_{VCL} = 1 + (50k/R_G)$. Where: R_G = Gain Set Resistor.

Common Mode Rejection Ratio: The ratio of input voltage range to the peak-to-peak change in offset voltage over this range.

Gain Equation Accuracy: The deviation of the actual closed loop gain from the predicted closed loop gain, $A_{VCL} = 1 + (50k/R_G)$ for the specified closed loop gain.

Input Bias Current: The current flowing at pin 5 and 6 under the specified operating conditions.

Input Offset Current: The difference between the input bias current at pins 5 and 6; i.e. $I_{OS} = |I_5 - I_6|$.

Input Stage Offset Voltage, V_{IOS} : The voltage which must be applied to the input pins to force the output to zero volts for $A_{VCL} = 100$.

Output Stage Offset Voltage, V_{OOS} : The voltage which must be applied to the input of the output stage to produce zero output voltage. It can be measured by measuring the overall offset at unity gain and subtracting V_{IOS} .

$$V_{OOS} = \left[V_{OS} \right]_{A_{VCL}=1} - \left[V_{OS} \right]_{A_{VCL}=1000}$$

Overall Offset Voltage:

$$V_{OS} = V_{IOS} + \frac{V_{OOS}}{A_{VCL}}$$

Power Supply Rejection Ratio: The ratio of the change in offset voltage, V_{OS} , to the change in supply voltage producing it.

Resistor, R_B : An optional resistor placed between pin 3 of the LH0036 and ground (or V^-) to reduce the input bias current.

Resistor, R_{BW} : An optional resistor placed between pin 1 of the LH0036 and ground (or V^-) to reduce the bandwidth of the output stage.

Resistor, R_G : A gain setting resistor connected between pins 4 and 7 of the LH0036 in order to program the gain from 1 to 1000.

Settling Time: The time between the initiation of an input step function and the time when the output voltage has settled to within a specified error band of the final output voltage.

LH0038/LH0038C True Instrumentation Amplifier

General Description

The LH0038/LH0038C is a precision true instrumentation amplifier (TIA) capable of amplifying very low level signals, such as thermocouple and low impedance strain gauge outputs. Precision thin film gain setting resistors are included in the package to allow the user to set the closed-loop gain from 100 to 2000. Since the resistors are of a homogeneous single chip construction, they track almost perfectly so that temperature variations of closed loop gain are virtually eliminated.

LH0038 exhibits excellent CMRR, PSRR, gain linearity, as well as extremely low input offset voltage, offset voltage drift and input noise voltage.

The devices are provided in a hermetically sealed 16-lead DIP. The LH0038 is guaranteed from -55°C to $+125^{\circ}\text{C}$; whereas the LH0038C is guaranteed from -25°C to $+85^{\circ}\text{C}$.

Features

- Ultra-low input offset voltage $25\ \mu\text{V typ.}, 100\ \mu\text{V max}$
- Ultra-low input offset drift $0.25\ \mu\text{V}/^{\circ}\text{C max}$
- Ultra-low input noise $0.2\ \mu\text{Vp-p}$
- Pin strap gain options 100, 200, 400, 500, 1k, 2k
- Excellent PSRR and CMRR 120 dB

Applications Information

THEORY OF OPERATION

The LH0038 is a 3-stage, true instrumentation amplifier composed of a well matched transistor differential pair, Q1 and Q2, a common-mode loop amplifier, A2 and A3, and a differential to single ended amplifier, A4. A simplified schematic is shown in Figure 3.

Current source, I_A , establishes a voltage across R14 of approximately 2V, which results in a 2V drop across R8 and R12. This constant voltage forces the first stage current to

be 20 μ A per side. The action of A2 and A3 is such that 20 μ A is maintained constant despite the presence of common-mode signals. The differential outputs of A2 and A3 are applied to differential amplifier, A4, which converts the signal to a single-ended output and provides gain of 5. The total gain of the amplifier is, therefore, the fixed gain of 5 multiplied by the gain of the composite input stage.

Applications Information (Continued)

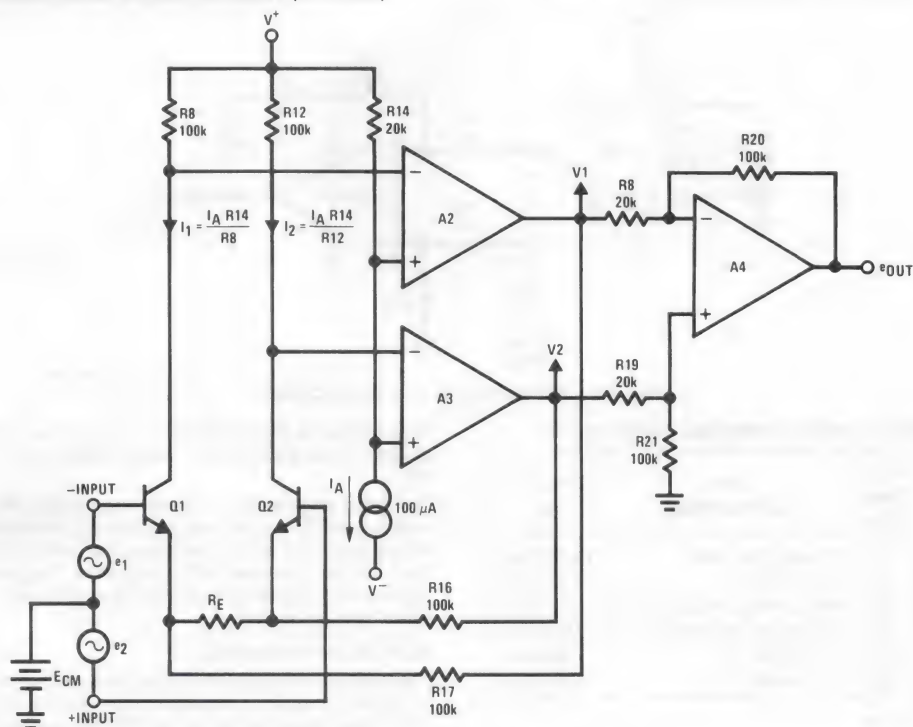

FIGURE 3. LH0038 Simplified Schematic

TL/H/5543-9

The closed loop gain of the composite amplifier may be better understood by referring to Figure 3. The Q1-A2 loop may be viewed as differential amplifier with the inverting input at the base and non-inverting input at the emitter. Combining small signal AC and large signal DC analysis =

$$v_1 = e_1 \left(\frac{R_{17} + R_E}{R_E} \right) - e_2 \left(\frac{R_{17}}{R_E} \right) + E_{CM} - V_{BE1} - I_1 R_{17} \quad (1)$$

By similar analysis:

$$v_2 = e_2 \left(\frac{R_{16} + R_E}{R_E} \right) - e_1 \left(\frac{R_{16}}{R_E} \right) + E_{CM} - V_{BE2} - I_2 R_{16} \quad (2)$$

For $I_1 \equiv I_2$, $R_{17} \equiv R_{16}$, $V_{BE1} \equiv V_{BE2}$, subtracting equation (1) from (2) results in:

$$v_2 - v_1 = (e_2 - e_1) \left(\frac{R_{16} + R_E}{R_E} \right) + (e_2 - e_1) \left(\frac{R_{16}}{R_E} \right) \quad (3)$$

$$\frac{v_2 - v_1}{e_2 - e_1} = \frac{2R_{16}}{R_E} + 1 \quad (4)$$

The differential input voltage ($v_2 - v_1$) is amplified by the closed loop gain of A4:

$$e_{OUT} = (A_{VCL4}) (e_2 - e_1) \quad (5)$$

where:

$$A_{VCL4} = \frac{R_{20}}{R_8} = 5.00$$

$$A_{VCL} = 5 \left(\frac{2R_{16}}{R_E} + 1 \right) \quad (6)$$

As an example, with all gain pins open, $R_E = 10.525 \text{ k}\Omega$, and;

$$A_{VCL} = 5 \left(\frac{(2)(100k)}{R_E} + 1 \right) = 100.0 \quad (7)$$

All other closed loop gain configurations place a precision resistor in parallel with R_E ($R_9 + R_{10}$). For example, for a gain of 200, pin 6 is connected to pin 10 and the gain is predicted by:

$$A_{VCL} = 5.00 \left[\frac{(2)(100k)}{(10.526) \parallel (10.000k)} + 1 \right] = (5.00)(40) = 200 \quad (8)$$

CLOSED LOOP GAIN CONSIDERATIONS USING INTERNAL RESISTORS

Table 1 summarizes the primary gain configurations available with the LH0038. Obviously, other gains are possible. Using the internally supplied resistors has the advantage that R_{16} , R_{17} , and R_E all track thermally, minimizing the device's gain error as a function of temperature.

Gain adjustment by paralleling or series padding internally supplied resistors is generally discouraged since external resistors will generally not thermally track. It is recommended that the gain adjustment be done in a subsequent stage as shown in Figure 4.

Applications Information (Continued)

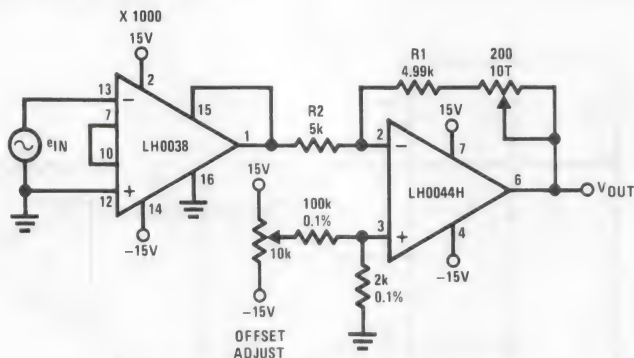

FIGURE 4. Recommended Gain Adjust Circuit

TL/H/5543-10

TABLE I. LH0038 Internal Gain Configurations

Overall Gain	First Stage Gain	Pin Configuration	Effective R_E
100	20	All Gain Pins Open	10.5260 k Ω
200	40	Pin 6 to Pin 10	5.1281 k Ω

1000	200	Pin 7 to Pin 10	1.0050 k Ω
2000	400	Pin 8 to Pin 10	0.5013 k Ω

GUARD DRIVE

The LH0038 is provided with a guard drive output, which will always be at the input common-mode voltage. The guard

drive amplifier is short-circuit proof and is capable of driving several thousand pF without danger of latch-up or oscillation.

The guard drive tied to a shielded input cable will greatly reduce noise pick-up, and also improve AC CMRR by maintaining the shield at the common-mode voltage. Figure 5 illustrates the proper use of the guard drive. The guard drive output is also connected to the case to provide electrostatic shielding to the system.

REMOTE OUTPUT SENSE

The feedback network of the LH0038 may be closed directly at the load in order to eliminate errors due to lead resistance. Also, a unity gain buffer; e.g. LH0002, may be included within the feedback loop to increase output current capability as shown in Figure 7.

FIGURE 7. Output Buffer Connection

TL/H/5543-13

OFFSET NULL

Offset of the LH0038 is trimmed by the factory to a very low value. The offset may be further trimmed using a 10 kΩ, 10 turn, 100 ppm/°C potentiometer as shown in Figure 8. However, a drift increase of 0.3 μV/°C will be caused for each 100 μV of offset adjusted. The recommended offset null is shown in Figure 4 and is accomplished in the following stage.

BIAS CURRENT CONSIDERATIONS

The LH0038 exhibits bias current of approximately 50 nA per side, and requires a path to ground or supply. The practical limitation to the maximum resistance between the inputs and ground is dictated by negative common-mode range as shown in Figure 9. For example, for $V_{CM} = -10V$, $R_{CM} \leq 20 M\Omega$.

The LH0038 input stage bias was optimized for minimum voltage noise so the input bias currents are higher than might otherwise be expected. Note, however, that the input currents are very well matched, resulting in an offset current value much lower than one might infer from the bias current. In order to take advantage of this low offset current, the source impedances at both inputs should be matched to minimize DC drift. Further, bias current is relatively constant with temperature (as opposed to an FET stage), so one can consider bias current compensation schemes such as shown in Figure 10. The danger with such techniques is that the offset current and noise contributed by the bias current compensator will dominate the system noise.

Definition of Terms

Bandwidth: That frequency at which the voltage gain is reduced to 3 dB below the low frequency.

Common-Mode Rejection Ratio, CMRR: The ratio of the input common-mode voltage range to the peak-to-peak change in input offset voltage over this range.

Input Offset Voltage, V_{IOS} : The voltage which must be applied to the inputs to force the outputs of the input stage to 0V. V_{IOS} can be calculated by measuring V_{OS} at closed loop gains of 100 and 2000 and using the following equation:

$$V_{IOS} = \frac{(V_{OS})_{2k} - (V_{OS})_{100}}{1900}$$

Where:

$(V_{OS})_{2k}$ = overall offset voltage for $A_{VCL} = 2k$.

$(V_{OS})_{100}$ = overall offset voltage for $A_{VCL} = 100$.

Gain Non-Linearity: The deviation of the gain from a straight line drawn through the end points expressed as a percent of full-scale (10V for operations on $\pm 15V$ supply). Note that this is a more stringent specification than deviation from the best straight line and is double the number that would be specified if the percentage were based on a 20V ($\pm 10V$) range.

Guard Voltage Error: The voltage difference between the guard drive output and the average of the 2 input voltages.

Input Bias Current, I_B : The average of the 2 input currents.

Input Common-Mode Voltage Range, V_{INCM} : The range of voltages on the input terminals for which the amplifier is operational. Note that the specifications are not guaranteed over the full common-mode voltage range unless specifically stated.

Input Offset Current, I_{OS} : The difference in the currents into the 2 input terminals when the output is at zero.

Input Resistance: The ratio of the change in input voltage to the change in input current on either input with the other grounded.

Overall Offset Voltage, V_{OS} : The output voltage when both inputs are connected to 0V. V_{OS} is composed of input amplifier offset voltage effects, V_{IOS} , and output amplifier effects, V_{OOS} . It is given by:

$$V_{OS} = (A_{VCL}) (V_{IOS}) - V_{OOS}$$

Where:

A_{VCL} = closed loop gain = 100 to 2k

V_{IOS} = input stage offset voltage

V_{OOS} = output stage offset voltage

Output Offset Voltage, V_{OOS} : The output voltage when the outputs of the input stage are forced to 0V. V_{OOS} may be calculated by measuring V_{OS} at closed loop gains of 100 and 2000 and using the following equation:

$$V_{OOS} = \frac{(20) (V_{OS})_{100} - (V_{OS})_{2k}}{19}$$

Where:

$(V_{OS})_{100}$ = overall offset voltage for $A_{VCL} = 100$

$(V_{OS})_{2k}$ = overall offset voltage for A_{VCL}

Output Voltage, V_O : The peak output voltage swing, referred to zero.

Offset Voltage Temperature Drift, $\Delta V_{IOS}/\Delta T$: The average drift rate of offset voltage for a thermal variation from room temperature to the indicated temperature extreme.

Power Supply Rejection Ratio, PSRR: The ratio of the change in input offset voltage to the change in power supply voltages producing it.

Settling times, t_s : The time between the initiation of the input step function and the time when the output voltage has settled to within a specified error band of the final output voltage.

Slew Rate, S_r : The internally-limited rate of change in output voltage with a large-amplitude step function applied to the input.

Supply Current, $\pm I_S$: The current required from the power supply to operate the amplifier with no load and the output midway between the supplies.

Supply Voltage Range: The range of voltages on the supply terminals for which the device is operational. Note that the specifications are not guaranteed over the full supply voltage range unless specifically stated.

Transient Response, t_r : The closed-loop step-function response of the amplifier under small-signal conditions.

Unity Gain Bandwidth: The frequency range from DC to the frequency where the amplifier open loop gain rolls off to 1.

Closed Loop Gain, A_{VCL} : The ratio of output voltage to input voltage under the stated conditions of source resistance (R_S) and load resistance (R_L).

Voltage Gain Error: The deviation in percent between the ideal voltage gain and the value obtained when the device is configured for that gain.

LH0084/LH0084C Digitally-Programmable-Gain Instrumentation Amplifier

General Description

The LH0084/LH0084C is a self-contained, high speed, high accuracy, digitally-programmable-gain instrumentation amplifier. It consists of paired FET-input variable-gain voltage-follower input stages followed by a differential-to-single-ended output stage. The input stage is programmable in accurate gain steps of 1, 2, 5, or 10 controlled by the logic levels of a 2-bit TTL-compatible digital input word. For additional flexibility, the output stage is pin-strappable to fixed gains of 1, 4, or 10 for an overall gain range of 1 to 100.

Applications include increased dynamic range A-to-D converters, test systems, and post multiplexer amplifier for data acquisition systems.

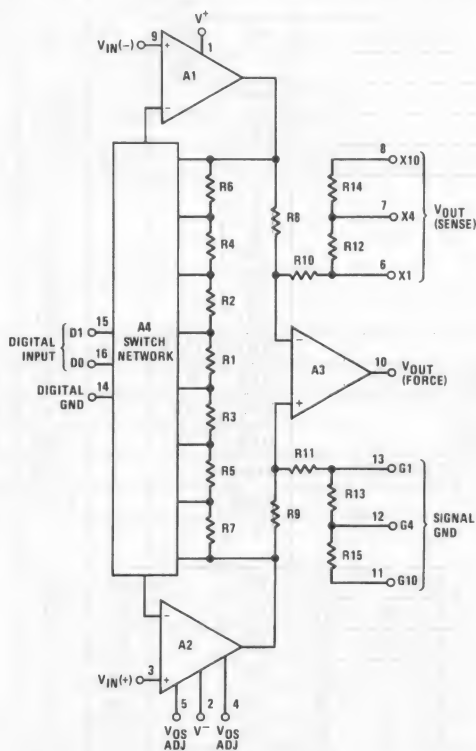

The device exhibits high input impedance, low offset voltage, high PSRR, high speed, and excellent gain accuracy and gain non-linearity.

The LH0084 is guaranteed from -55°C to $+125^{\circ}\text{C}$. The LH0084C is guaranteed from -25°C to $+85^{\circ}\text{C}$. Both devices are provided in a hermetically sealed 16-lead dual-in-line metal package.

Features

- Excellent gain accuracy and low gain non-linearity 0.075% max
0.01% typ
- Extremely low gain drift 1 ppm/ $^{\circ}\text{C}$ typ
10 ppm/ $^{\circ}\text{C}$ max
- High input impedance $10^{11}\Omega$ typ
- High PSRR 70 dB min
- TTL compatible digital inputs
- High speed, settling to 0.1% 4 μs max

Note 1: Improper supply power-on sequence may damage the device. See Power Supply Connection section under Applications Information.

Note 2: For supply voltages less than $\pm 15V$ the maximum input voltage is equal to the supply voltage.

Note 3: These parameters are specified at junction temperature, T_J . In normal operation the junction temperature rises above the ambient temperature, T_A , as a result of internal power dissipation, P_D . $T_J = T_A + \theta_{JA}P_D$ where θ_{JA} is the thermal resistance from junction to ambient.

Note 4: The input bias currents are junction leakage currents which approximately double for every $10^\circ C$ increase in the junction temperature.

Note 5: See Typical Performance Characteristics for Thermal Resistance Information.

Note 6: Refer to RETS0084D for LH0084D military specifications.

Applications Information

THEORY OF OPERATION

The LH0084 is a digitally-programmable-gain true-instrumentation amplifier composed of a variable-gain voltage-follower input stage (A1 and A2), followed by a differential output stage (A3). The schematic is shown in Figure 4.

The input stage contains matched high-speed FET-input op amps (A1 and A2). A high-stability temperature-compensated resistor network (R1 through R7) controls feedback ratios at the inverting inputs of op amps A1 and A2 via FET switches S1A–S4A and S1B–S4B. Since the FET switches are in series with the op amp input impedance their resistance match and temperature drift do not degrade the gain accuracy of the instrumentation amplifier. The FET switches are controlled through a 1-of-4 decoder and switch driver, by the logic levels applied at the digital input terminals D1

and D0 and set the gain of the input stage as shown in Table I.

If, for example, D1 is High ($\geq 2.0V$) and D0 is Low ($\leq 0.7V$), FET switch pair S3A and S3B will be closed (and all remaining switches open). The input stage gain, $A_{V(1)}$, can then be shown to be:

$$\begin{aligned} A_{V(1)} &= \frac{V_2 - V_1}{V_{IN(+)} - V_{IN(-)}} \\ &= 1 + \frac{R_4 + R_5 + R_6 + R_7}{R_1 + R_2 + R_3} \\ &= 1 + \frac{6k + 6k + 10k + 10k}{4k + 2k + 2k} \\ &= 5 \end{aligned}$$

Schematic Diagram

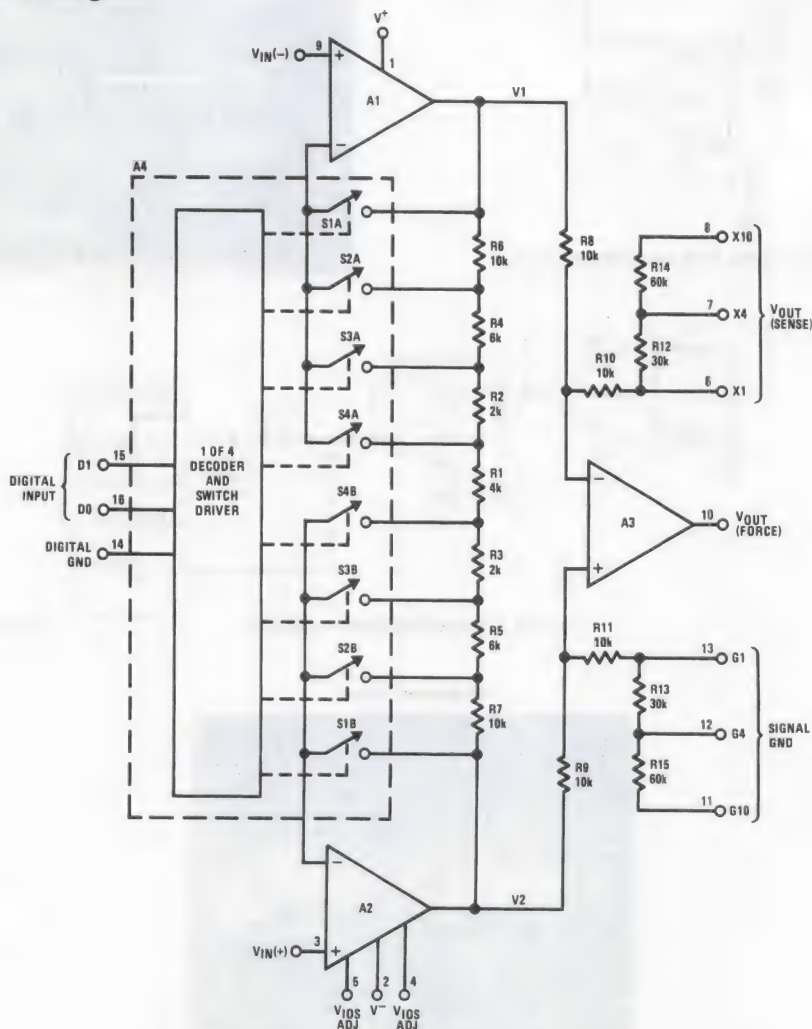

FIGURE 4

TL/H/5651-6

Applications Information (Continued)

TABLE I. Gain Truth Table and Connection Table

Digital Inputs		1st Stage Gain $A_{V(1)}$	Pin Connections	2nd Stage Gain $A_{V(2)}$	Overall Gain A_V
D1	D0				
0	0	1	6-10, 13-GND	1	1
0	1	2			2
1	0	5			5
1	1	10			10
0	0	1	7-10, 12-GND	4	4
0	1	2			8
1	0	5			20
1	1	10			40
0	0	1	8-10, 11-GND	10	10
0	1	2			20
1	0	5			50
1	1	10			100

The output stage, consisting of op amp A3 and resistors R8 through R15, converts the voltage difference at the output of the input stage, V2 minus V1, to a single-ended output. For increased flexibility of the LH0084, the output stage gain is pin-strappable by selecting R10, R10+R12, or R10+R12+R14 as feedback resistor for A3. The ratios of these resistors to the differential stage input resistor R3 are kept very accurate to maintain the excellent overall gain accuracy of the device. The output stage gain, $A_{V(2)}$, is equal to the feedback resistance divided by the input resistance. Thus with, for example, Pin 7 wired to Pin 10, that gain would be:

$$\begin{aligned}
 A_{V(2)} &= \frac{V_{OUT}}{V_2 - V_1} \\
 &= \frac{R10 + R12}{R8} \\
 &= \frac{10K + 30K}{10k}
 \end{aligned} \quad (2)$$

To preserve the high common-mode rejection ratio of the output stage, the ground sense resistor, R11, R11+R13 or R11+R13+R15, must match the feedback resistor used.

The overall gain of the LH0084 is therefore:

$$\begin{aligned}
 A_V &= \frac{V_{OUT}}{V_{IN(+)} - V_{IN(-)}} \\
 &= \frac{V_2 - V_1}{V_{IN(+)} - V_{IN(-)}} \cdot \frac{V_{OUT}}{V_2 - V_1} \\
 &= A_{V(1)} \cdot A_{V(2)}
 \end{aligned} \quad (3)$$

The different gains available are in the range of 1 through 100 and are summarized in Table I.

POWER SUPPLY CONNECTIONS

Proper power supply connections are shown in *Figure 5*. The power supplies should be bypassed to ground as close as possible to device supply pins. For optimum high speed performance V^+ and V^- should be decoupled with a 0.01 μ F ceramic disc in parallel with a 1 μ F electrolytic capacitor.

The two ground pins, analog and digital grounds, should be connected together as close to the device as possible, preferably with a ground plane underneath the device. If this is not possible, the grounds should be connected together locally with back-to-back diodes and hard-wired together off-board. If a ground reference offset is used, it must be low impedance compared to the ground sense resistance to avoid CMRR degradation.

Care must be taken in the supply power-on sequence. The LH0084 may suffer irreversible damage if the V^+ supply is applied prior to the powering on the V^- supply. In most applications using dual tracking supplies and with the device supply pins adequately bypassed, this will not present a problem. If this cannot be guaranteed, a germanium or Schottky protection diode should be connected between the digital ground pin and the V^- pin as shown in *Figure 5*.

*See text

TL/H/5651-7

FIGURE 5. Power Supply Connections

Applications Information (Continued)

SIGNAL CONNECTIONS

The input signals should be connected as shown in *Figure 6*. To minimize errors, $R_S(+)$, $R_S(-)$ and R_{CM} should be kept as small as possible.

The output connections are also shown in *Figure 6*. The feedback leads should be kept short as should the ground sense in order to minimize lead resistance and parasitic capacitance.

OFFSET AND GAIN ADJUSTMENTS

Special care must be taken when using external offset adjustment. Since the LH0084 is a 2-stage amplifier with each stage contributing offset errors, and the amplifier presumably is used at several different gains, it is important to realize that the offsets of both the 1st and the 2nd stages must be nulled to maintain zero offset referred to output (RTO) at all gain settings.

In general, it is recommended that the input stage offset (V_{IOS}) be adjusted with a potentiometer as shown in *Figure 7*. The output stage offset (V_{OOS}) is ideally adjusted at a subsequent gain stage (i.e. sample-and-hold or A-to-D converter), but if this is impractical, it may also be done as shown in *Figure 7*.

Recommended offset adjust procedure is as follows: Initially set both pots to center positions and short both inputs of the LH0084 to ground.

- Set the input stage gain to 1 (pull D1 and D0 low). Measure the output voltage, V_{OUT1} .
- Set the input stage gain to 10 (pull D1 and D0 high). Measure the new output voltage, V_{OUT2} .
- Calculate the portion of V_{OUT2} contributed by the output stage offset per the equation:

$$V_{OOS} = \frac{1}{9}(10 \cdot V_{OUT1} - V_{OUT2}) \quad (4)$$

- While maintaining an input stage gain of 10, adjust the input offset voltage (V_{IOS}) potentiometer until the output voltage is equal to the voltage calculated in Equation (4).
- Change the input back to a gain of 1 and adjust the output offset voltage (V_{OOS}) potentiometer until the output voltage is zero.

FIGURE 6. Signal Connections

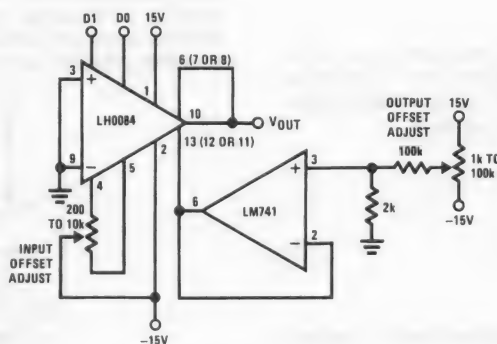

FIGURE 7. Offset Adjust Circuit

TL/H/5651-8

Applications Information (Continued)

An alternate offset adjust scheme is shown in *Figure 8*. The offset should be zeroed after each time the gain is changed or when the op amp integrator drift warrants a new zero pulse. An additional advantage of this adjustment technique is that it can also be used to cancel out offset voltage drift and common-mode voltage error contributions.

External gain adjustment is generally discouraged since gain accuracy can be optimized for one gain setting only. If gain adjustment is required, however, it should be done at a subsequent gain stage.

LOGIC CONNECTIONS

The digital inputs D1 and D0 are referenced to the digital

ground. The device interfaces directly to TTL and, with pull-down resistors, to CMOS.

Interfacing with microprocessors will usually require a latch. A circuit using full 6-bit wide address decode and write strobe is shown in *Figure 9*.

REMOTE OUTPUT SENSE

The feedback resistors of the LH0084 can be connected directly at the load in order to eliminate errors due to lead resistance (*Figure 10*).

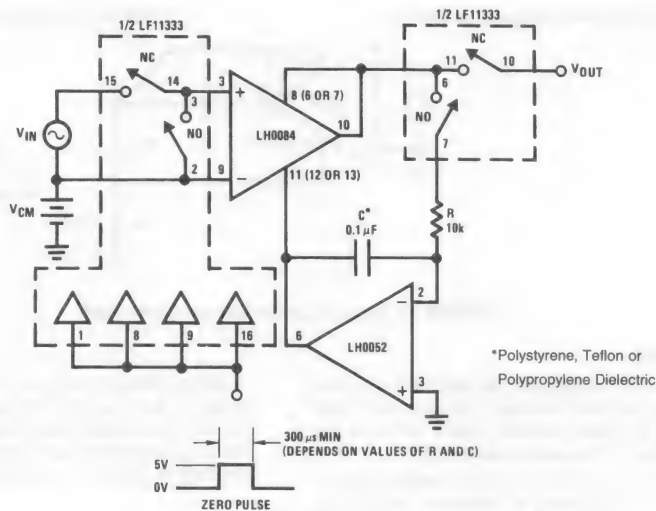

FIGURE 8. Auto Zero Circuit

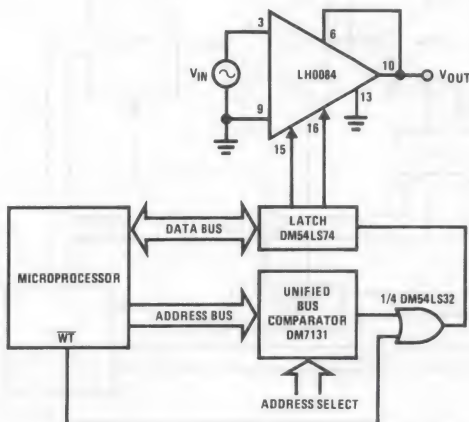

FIGURE 9. Typical Microprocessor Interface

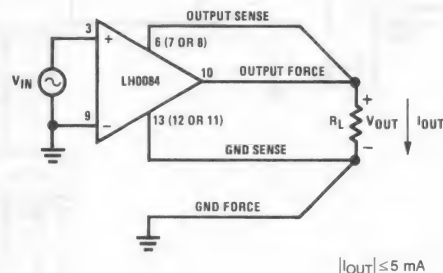

FIGURE 10. Remote Sense Connection

Applications Information (Continued)

Also, a unity gain buffer, such as the LH0033, may be included in the feedback loop for increased current drive capability as shown in *Figure 11*.

FIGURE 11. Buffered Output Connection

The output sense feature can also be used in other ways such as output offset, *Figure 12*, or current source output, *Figure 13*.

FIGURE 12. Output Offset Connection

FIGURE 13. Output Current Source Connection

TL/H/5651-10

Applications

The LH0084 is ideal for application in increased dynamic range A-to-D converters, test systems, process control, and multi-channel data acquisition system. *Figure 14* shows the device used in a typical data acquisition system.

A software offset and gain error correction scheme is shown in *Figure 15*. By first selecting a multiplexer input con-

nected to analog ground, and then selecting a channel connected to a reference of known value, the overall system gain and offset errors can be calculated. For all subsequent readings, offset and gain corrections can be made mathematically by solving a simple first-order equation in software.

FIGURE 15. Software System Offset and Gain Calibration Circuit

Definition of Terms

Input Offset Voltage, V_{IOS} : The voltage which must be applied to the inputs to force the output of the input stage to 0V. V_{IOS} can be calculated by measuring V_{OS} (RTO) at input stage gains of 1 and 10 and using the following equation:

$$V_{IOS} = \frac{1}{9} (V_{OS|_{AV=10}} - V_{OS|_{AV=1}})$$

where:

$V_{OS|_{AV=10}}$ = Overall offset (RTO) for $A_V = 10$

$V_{OS|_{AV=1}}$ = Overall offset (RTO) for $A_V = 1$

Input Offset Current, I_{OS} : The difference in the currents into the 2 analog input terminals at 0V.

Input Bias Current, I_B : The average of the currents into the 2 analog input terminals at 0V.

Input Resistance, R_{IN} : Common-mode input resistance is the change in input voltage range divided by the change in input bias current with both analog inputs at the same voltage. Differential input resistance is the change in input voltage at one input terminal divided by the change in input current at the other input terminal which is kept still at 0V.

Input Voltage Range, V_{IN} : The voltage range for which the device is operational.

Common-Mode Rejection Ratio, CMRR: The ratio of the input common-mode voltage range to the change in input offset voltage over this range.

Power Supply Rejection Ratio, PSRR: The ratio of the specified change in supply voltage to the change in input offset voltage over this range.

Voltage Gain, A_V : The ratio of output voltage change to the input voltage change producing it.

Gain Error: The deviation in percent between the ideal voltage gain and the value obtained when the device is configured for that gain.

Gain Non-Linearity: The deviation of the gain from a straight line drawn through the end-points expressed as a percent of full-scale (10V for operation with $\pm 15V$ supply). For testing purposes it is the difference between positive swing gain (0V to 10V) and average gain ($-10V$ to 10V) or between negative swing gain (0V to $-10V$) and average gain.

Output Stage Offset Voltage, V_{OOS} : The voltage which must be applied to the input of the output stage for the output to be forced to 0V. V_{OOS} can be calculated by measuring V_{OS} (RTO) at input stage gains of 1 and 10 and applying the following equation:

$$V_{OOS} = \frac{1}{9} (10 \cdot V_{OS|_{AV=1}} - V_{OS|_{AV=10}})$$

where:

$V_{OS|_{AV=1}}$ = Overall offset (RTO) for $A_V = 1$

$V_{OS|_{AV=10}}$ = Overall offset (RTO) for $A_V = 10$

Offset Voltage (Referred to Output), $V_{OS(RTO)}$: The output voltage when both inputs are connected to 0V. V_{OS} is composed of input offset voltage, V_{IOS} , and output offset voltage, V_{OOS} , and is a function of amplifier gain. The overall offset voltage is given by:

$$V_{OS(RTO)} = A_{V(2)} (A_{V(1)} V_{IOS} + V_{OOS})$$

where:

V_{IOS} = Input offset voltage

V_{OOS} = Output stage offset voltage

$A_{V(1)}$ = Input stage gain

$A_{V(2)}$ = Output stage gain

Definition of Terms (Continued)

Output Voltage Swing, V_O : The peak output voltage swing referenced to ground into specified load.

Output Short-Circuit Current, I_O : The current supplied by the device with the output connected directly to ground.

Output Resistance, r_O : The ratio of change in output voltage to change in output current around zero output.

Supply Voltage Range, V_S : The supply voltage range for which the device is operational.

Supply Current, I_S : The current required from the supply to operate the device with zero load and with the analog as well as the digital inputs at 0V.

Power Dissipation, P_D : The power dissipated in the device with zero load and with the analog as well as the digital inputs at 0V.

Digital "1" Input Voltage, V_{IH} : Minimum voltage required at the digital input to guarantee a high logic state.

Digital "0" Input Voltage, V_{IL} : Maximum voltage required at the digital input to guarantee a low logic state.

Digital "1" Input Current, I_{IH} : The current into a digital input at specified logic level.

Digital "0" Input Current, I_{IL} : The current into a digital input at specified logic level.

Average Input Offset Voltage Drift, $\Delta V_{IOS}/\Delta T$: The ratio of input offset voltage change from 25°C to either temperature extreme divided by the temperature range.

Average Output Offset Voltage Drift, $\Delta V_{OOS}/\Delta T$: The ratio of output offset voltage change from 25°C to either temperature extreme divided by the temperature range.

Average Gain Temperature Coefficient, $\Delta A_V/\Delta T$: The ratio of change in gain from 25°C to either temperature extreme divided by the temperature range.

Small Signal Bandwidth, BW: The frequency at which the device gain changes from the low frequency gain by a specified amount.

Power Bandwidth, PBW: Maximum frequency for which the output swing is a large signal sinewave without noticeable distortion.

Slew Rate, SR: The internally limited rate of change in output voltage with a large amplitude step function applied at the input.

Settling Time, t_s : The time between the initiation of an input step function and the time when the output voltage has settled to within a specified error band of the final output voltage.

Gain Switching Time: The time between the initiation of a gain logic change and the time when the final gain switches are closed. It includes overdrive recovery time, but not settling to final value.

Equivalent Input Noise Voltage, E_N : The rms of peak noise voltage referred to the input (RTI) over a specified frequency band.

Equivalent Input Noise Current, I_N : The rms of peak noise current referred to the input (RTI) over a specified frequency band.

LM221/LM321/LM321A Precision Preamplifiers

General Description

The LM121 series are precision preamplifiers designed to operate with general purpose operational amplifiers to drastically decrease dc errors. Drift, bias current, common mode and supply rejection are more than a factor of 50 better than standard op amps alone. Further, the added dc gain of the LM121 decreases the closed loop gain error.

The LM121 series operates with supply voltages from $\pm 3\text{V}$ to $\pm 20\text{V}$ and has sufficient supply rejection to operate from unregulated supplies. The operating current is programmable from $5\text{ }\mu\text{A}$ to $200\text{ }\mu\text{A}$ so bias current, offset current, gain and noise can be optimized for the particular application while still realizing very low drift. Super-gain transistors are used for the input stage so input error currents are lower than conventional amplifiers at the same operating current. Further, the initial offset voltage is easily nulled to zero.

The extremely low drift of the LM121 will improve accuracy on almost any precision dc circuit. For example, instrumentation amplifier, strain gauge amplifiers and thermocouple amplifiers now using chopper amplifiers can be made with

the LM121. The full differential input and high common-mode rejection are another advantage over choppers. For applications where low bias current is more important than drift, the operating current can be reduced to low values. High operating currents can be used for low voltage noise with low source resistance. The programmable operating current of the LM121 allows tailoring the input characteristics to match those of specialized op amps.

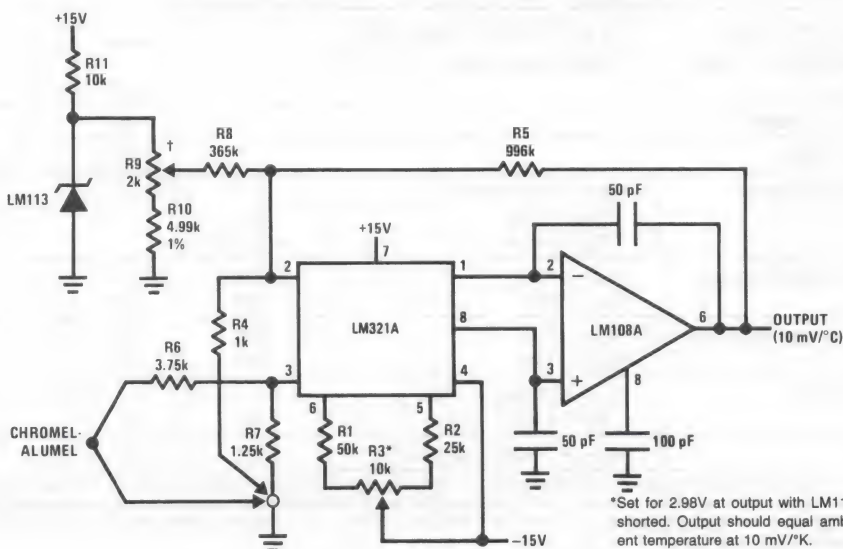

The LM221 is specified over a -25°C to $+85^{\circ}\text{C}$ range and the LM321 over a 0°C to $+70^{\circ}\text{C}$ temperature range.

Features

- Guaranteed drift of LM321A— $0.2\text{ }\mu\text{V}/^{\circ}\text{C}$
- Guaranteed drift of LM221 series— $1\text{ }\mu\text{V}/^{\circ}\text{C}$
- Offset voltage less than 0.4 mV
- Bias current less than 10 nA at $10\text{ }\mu\text{A}$ operating current
- CMRR 126 dB minimum
- 120 dB supply rejection
- Easily nulled offset voltage

Typical Applications

Thermocouple Amplifier with Cold Junction Compensation

TL/H/7769-1

Note 1: The maximum junction temperature of the LM321A is 85°C . For operating at elevated temperature, devices in the TO-5 package must be derated based on a thermal resistance of $150^{\circ}\text{C}/\text{W}$, junction to ambient, or $45^{\circ}\text{C}/\text{W}$, junction to case. For the flat package, the derating is based on a thermal resistance of $185^{\circ}\text{C}/\text{W}$ when mounted on a $\frac{1}{4}$ inch thick epoxy glass board with ten, 0.03 inch wide, 2 ounce copper conductors. The thermal resistance of the dual-in-line package is $100^{\circ}\text{C}/\text{W}$ junction to ambient.

Note 2: The inputs are shunted with back-to-back diodes in series with a 500Ω resistor for overvoltage protection. Therefore, excessive current will flow if a differential input voltage in excess of 1V is applied between the inputs.

Note 3: For supply voltages less than $\pm 15\text{V}$, the absolute maximum input voltage is equal to the supply voltage.

Note 4: These specifications apply for $\pm 5 \leq V_S \leq \pm 20\text{V}$ and $-55^{\circ}\text{C} \leq T_A \leq +125^{\circ}\text{C}$, unless otherwise specified. With the LM221A, however all temperature specifications are limited to $-25^{\circ}\text{C} \leq T_A \leq +85^{\circ}\text{C}$, and for the LM321A the specifications apply over a 0°C to $+70^{\circ}\text{C}$ temperature range.

Note 5: External precision resistor—0.1%—can be placed from pins 1 and 8 to 7 increase positive common-mode range.

Note 1: The maximum junction temperature of the LM221 is 100°C. The maximum junction temperature of the LM321 is 85°C. For operating at elevated temperature, devices in the TO-5 package must be derated based on a thermal resistance of 150°C/W, junction to ambient, or 45°C/W, junction to case. For the flat package, the derating is based on a thermal resistance of 185°C/W when mounted on a 1/8 inch thick epoxy glass board with ten, 0.03 inch wide, 2 ounce copper conductors. The thermal resistance of the dual-in-line package is 100°C/W junction to ambient.

Note 2: The inputs are shunted with back-to-back diodes in series with a 500 Ω resistor for overvoltage protection. Therefore, excessive current will flow if a differential input voltage in excess of 1V is applied between the inputs.

Note 3: For supply voltages less than ±15V, the absolute maximum input voltage is equal to the supply voltage.

Note 4: These specifications apply for $\pm 5 \leq V_S \leq \pm 20\text{V}$ and $-55^\circ\text{C} \leq T_A \leq +125^\circ\text{C}$, unless otherwise specified. With the LM221, however all temperature specifications are limited to $-25^\circ\text{C} \leq T_A \leq +85^\circ\text{C}$, and for the LM321 the specifications apply over a 0°C to +70°C temperature range.

Note 5: External precision resistor —0.1%— can be placed from pins 1 and 8 to 7 increase positive common-mode range.

Frequency Compensation

UNIVERSAL COMPENSATION

The additional gain of the LM321 preamplifier when used with an operational amplifier usually necessitates additional frequency compensation. When the closed loop gain of the op amp with the LM321 is less than the gain of the LM321 alone, more compensation is needed. The worst case situation is when there is 100% feedback—such as a voltage follower or integrator—and the gain of the LM321 is high. When high closed loop gains are used—for example $A_V = 1000$ —and only an addition gain of 200 is inserted by the LM321, the frequency compensation of the op amp will usually suffice.

The frequency compensation shown here is designed to operate with any unity-gain stable op amp. Figure 1 shows the basic configuration of frequency stabilizing network. In operation the output of the LM321 is rendered single ended by a 0.01 μF bypass capacitor to ground. Overall frequency compensation then is achieved by an integrating capacitor around the op amp.

$$\text{Bandwidth at unity-gain} \approx \frac{12}{2\pi R_{SET} C}$$

$$\text{for 0.5 MHz bandwidth } C = \frac{4}{10^6 R_{SET}}$$

For use with higher frequency op amps such as the LM118 the bandwidth may be increased to about 2 MHz.

If the closed loop gain is greater than unity, "C" may be decreased to:

$$C = \frac{4}{10^6 A_{CL} R_{SET}}$$

ALTERNATE COMPENSATION

The two compensation capacitors can be made equal for improved power supply rejection. In this case the formula for the compensation capacitor is:

$$C = \frac{8}{10^6 A_{CL} R_{SET}}$$

Typical Applications

*Offset adjust.

†See table for frequency compensation.

LM363 Precision Instrumentation Amplifier

General Description

The LM363 is a monolithic true instrumentation amplifier. It requires no external parts for fixed gains of 10, 100 and 1000. High precision is attained by on-chip trimming of offset voltage and gain. A super-beta bipolar input stage gives very low input bias current and voltage noise, extremely low offset voltage drift, and high common-mode rejection ratio. A new two-stage amplifier design yields an open loop gain of 10,000,000 and a gain bandwidth product of 30 MHz, yet remains stable for all closed loop gains. The LM363 operates with supply voltages from $\pm 5V$ to $\pm 18V$ with only 1.5 mA current drain.

The LM363's low voltage noise, low offset voltage and offset voltage drift make it ideal for amplifying low-level, low-impedance transducers. At the same time, its low bias current and high input impedance (both common-mode and differential) provide excellent performance at high impedance levels. These features, along with its ultra-high common-mode rejection, allow the LM363 to be used in the most demanding instrumentation amplifier applications, replacing expensive hybrid, module or multi-chip designs. Because the LM363 is internally trimmed, precision external resistors and their associated errors are eliminated.

The 16-pin dual-in-line package provides pin-strappable gains of 10, 100 or 1000. Its twin differential shield drivers

eliminate bandwidth loss due to cable capacitance. Compensation pins allow overcompensation to reduce bandwidth and output noise, or to provide greater stability with capacitive loads. Separate output force, sense and reference pins permit gains between 10 and 10,000 to be programmed using external resistors.

On the 8-pin TO-5 package, gain is internally set at 10, 100 or 500 but may be increased with external resistors. The shield driver and offset adjust pins are omitted on the 8-pin versions.

The LM363 is rated for $0^{\circ}C$ to $70^{\circ}C$.

Features

- Offset and gain pretrimmed
- 12 nV/ \sqrt{Hz} input noise ($G=500/1000$)
- 130 dB CMRR typical ($G=500/1000$)
- 2 nA bias current typical
- No external parts required
- Dual shield drivers
- Available at $0.5 \mu V/^{\circ}C$ maximum drift
- Can be used as a high performance op amp
- Low supply current (1.5 mA typ)

Simplified Schematic (pin numbers in parentheses are for 8-pin package)

TL/H/5609-7

Theory of Operation

Referring to the Simplified Schematic, it can be seen that the input voltage is applied across the bases of Q1 and Q2 and appears between their emitters. If R_{E1-2} is the resistance across these emitters, a differential current equal to V_{IN}/R_{E1-2} flows from Q1's emitter to Q2's. The second stage amplifier shown maintains Q1 and Q2 at equal collector currents by negative feedback to Q4. The emitter currents of Q3 and Q4 must therefore be unbalanced by an amount equal to the current flow across R_{E1-2} . Defining $R_{E3-4} = R5 + R6$, the differential voltage across the emitters of Q4 to Q3 is equal to

$$\frac{V_{IN}}{R_{E1-2}} \times R_{E3-4}$$

This voltage divided by the attenuation factor

$$\frac{R4}{R3 + R4} = \frac{R2}{R1 + R2}$$

is equal to the output-to-reference voltage. Hence, the overall gain is given by

$$G = \frac{V_{OUT}}{V_{IN}} = \frac{R3 + R4}{R4} \times \frac{R_{E3-4}}{R_{E1-2}}$$

Application Hints

The LM363 was designed to be as simple to use as possible, but several general precautions must be taken. The differential inputs are directly coupled and need a return path to power supply common. Worst-case bias currents are only 10 nA for the LM363, so the return impedance can be as high as 100 M Ω . Ground drops between signal return and IC supply common should not be ignored. While the LM363 has excellent common-mode rejection, signals must remain within the proper common-mode range for this specification to apply. Operating common-mode range is guaranteed from -11V to $+13\text{V}$ with $\pm 15\text{V}$ supplies.

The high-gain (500 or 1000) versions have large gain-bandwidth products (15 MHz or 30 MHz) so board layout is fairly critical. The differential input leads should be kept away from output force and sense leads, especially at high impedances. Only 1 pF from output to positive input at 100 k Ω source impedance can cause oscillations. The gain adjust leads on the 16-pin package should be treated as inputs and kept away from the output wiring.

POWER SUPPLY

The LM363 may be powered from split supplies from $\pm 5\text{V}$ to $\pm 18\text{V}$ (or single-ended supplies from 10V to 36V). Positive supply current is typically 1.2 mA independent of supply voltage. The negative supply current is higher than the positive by the current drawn through the voltage dividers for the reference and sense inputs (typ 600 μA total). The LM363's excellent PSRR often makes regulated supplies unnecessary. Actually, supply voltage can be as low as 7V total but PSRR is severely degraded, so that well-regulated supplies are recommended below 10V total. Split supplies need not be balanced; output swing and input common-mode range will simply not be symmetrical with unbalanced supplies. For example, at $+12\text{V}$ and -5V supplies, input common-mode range is typically $+10.5\text{V}$ to -2V and output swing is $+11\text{V}$ to -4V .

When using ultra-low offset versions, best results are obtained at $\pm 15\text{V}$ supplies. For example, the LM363-500's offset voltage is guaranteed within 100 μV at $\pm 15\text{V}$ at 25°C . Running at $\pm 5\text{V}$ results in a worst-case negative PSRR error of 10V (-15V to -5V) multiplied by 3.2×10^{-6} (110 dB) or 32 μV , increasing the worst-case offset. Positive PSRR results in another 10 μV worst-case change.

INPUTS

The LM363 input circuitry is depicted in the Simplified Schematic. The input stage is run relatively rich (50 μA) for low voltage noise and wide bandwidth; super-beta transistors and bias-current cancellation (not shown) keep bias currents low. Due to the bias-current cancellation circuitry, bias current may be either polarity at either input. While input current noise is high relative to bias current, it is not significant until source resistance approaches 100 k Ω .

Input common-mode range is typically from 3V above V^- to 1.5V below V^+ , so that a large potential drop between the input signal and output reference can be accommodated. However, a return path for the input bias current must be provided; the differential input stage is not isolated from the supplies. Differential input swing in the linear region is equal to output swing divided by gain, and typically ranges from 1.3V at $G=10$ to 13 mV at $G=1000$.

Clamp diodes are provided to prevent zener breakdown and resulting degradation of the input transistors. At large input overdrives these diodes conduct, greatly increasing input currents. This behavior is illustrated in the I_{IN} vs V_{IN} plot in the Typical Performance Characteristics. (The graph is not symmetrical because at large input currents a portion of the current into the device flows out the V^- terminal.)

The input protection resistors allow a full 10V differential input voltage without degradation even at $G=1000$. At input voltages more than one diode drop below V^- or two diode drops above V^+ input, current increases rapidly. Diode clamps to the supplies, or external resistors to limit current to 20 mA, will prevent damage to the device.

REFERENCE AND SENSE INPUTS

The equivalent circuit is shown in the schematic diagram. Limitations for correct operation are as follows. Maximum differential swing between reference and sense pins is typically $\pm 15\text{V}$ ($\pm 10\text{V}$ guaranteed). If this limit is exceeded, the sense pin no longer controls the output, which pegs high or low. The negative common-mode limit is 1.5V below V^- . (This is permissible because R2 and R4 are returned to a node biased higher than V^- .) If large positive voltages are applied to the reference and sense pins, the common-mode range of the signal inputs begins to suffer as the drop across R13 and R16 increases. For example, at $\pm 15\text{V}$ supplies, $V_{REF}=V_{SENSE}=0\text{V}$, signal input range is typically -12V to $+13.5\text{V}$. At $V_{REF}=V_{SENSE}=15\text{V}$, signal input range drops to -11V to $+13.5\text{V}$. The reference and sense pin can be as much as 10V above V^+ as long as a restricted signal common-mode range (-10V min) can be tolerated.

For maximum bipolar output swing at $\pm 15\text{V}$ supplies, the reference pin should be returned to a voltage close to ground. At lower supply voltages, the reference pin need not be halfway between the supplies for maximum output swing. For example, at $V^+=+12\text{V}$ and $V^-=-5\text{V}$, grounding the reference pin still allows a $+11\text{V}$ to -4V swing. For single-supply systems, the reference pin can be tied to either supply if a single output polarity is all that is required. For a bipolar input and output, create a low impedance reference with an op amp and voltage divider or a regulator (e.g., LM336, LM385, LM317L). This forms the reference for all succeeding signal-processing stages. (Don't connect the reference terminal directly to a voltage divider; this degrades gain error.) See Figure 1.

FIGURE 1. Reference Connections (Continued)

OUTPUTS

The LM363's output can typically swing within 1V of the supplies at light loads. While specified to drive a $2\text{ k}\Omega$ load to $\pm 10\text{V}$, current limit is typically 15 mA at room temperature. The output can stably drive capacitive loads up to 400 pF. For higher load capacitance, the amplifier may be overcompensated. The output may be continuously shorted to ground without damaging the device.

OFFSET VOLTAGE

The LM363's offset voltage is internally trimmed to a very low value. Note that data sheet values are given at $T_j = 25^\circ\text{C}$, $V_{CM} = 0\text{V}$ and $V^+ = V^- = 15\text{V}$. For other conditions, warm-up drift, temperature drift, common-mode rejection and power supply rejection must be taken into account. Warm-up drift, due to chip and package thermal gradients, is an effect separate from temperature drift. Typical warm-up drift is tabulated in the Electrical Characteristics; settling time is approximately 5 minutes in still air. At load currents up to 5 mA, thermal feedback effects are negligible ($\Delta V_{OS} \leq 2\mu\text{V}$ at $G = 1000$).

Care must be taken in measuring the extremely low offset voltages of the high gain amplifiers. Input leads must be held isothermal to eliminate thermocouple effects. Oscillations, due to either heavy capacitive loading or stray capacitance from input to output, can cause erroneous readings. In either case, overcompensation will help. High frequency noise fed into the inputs may be rectified internally, and pro-

duce an offset shift. A simple low-pass RC filter will usually cure this problem (Figure 2). Use film type resistors for their low thermal EMF. In highly noisy environments, LC filters can be substituted for increased RF attenuation.

TL/H/5609-10

FIGURE 2. Low Pass Filter Prevents RF Rectification

Instrumentation amplifiers have both an input offset voltage (V_{IOS}) and an output offset voltage (V_{OOS}). The total input-referred offset voltage (V_{OSRTI}) is related to the instrumentation amplifier gain (G) as follows: $V_{OSRTI} = V_{IOS} + V_{OOS}/G$. The offset voltage given in the LM363 specifications is the total input-referred offset. As long as only one gain is used, offset voltage can be nulled at either input or output as shown in Figures 3a and 3b. When the 16-pin device is used at multiple gain settings, both V_{IOS} and V_{OOS} should be nulled to get minimum offset at all gains, as shown in Figure 3c. The correct procedure is to trim V_{OOS} for zero output at $G = 10$, then trim V_{IOS} at $G = 1000$.

Application Hints (Continued)

COMPENSATION AND OUTPUT CLAMPING

The LM363 is internally compensated for unity feedback from output to sense. Increasing gain with external dividers will decrease the bandwidth and increase stability margin. Without external compensation, the amplifier can stably drive capacitive loads up to 400 pF. When used as an op amp (sense and reference pins grounded, feedback to inverting input), the LM363 is stable for gains of 100 or more. For greater stability, the device may be over-compensated as in Figure 6. Tables I and II depict suggested compensation components along with the resulting changes in large and small signal bandwidth for the 8-pin and 16-pin packages, respectively.

Note that the RC network from pin 8 of the 8-pin device to ground has a large effect on power bandwidth, especially at low gains. The Miller capacitance utilized for the 16-pin device permits higher slew rate and larger load capacitance for the same bandwidth, and is preferred when bandwidth must be greatly reduced (e.g., to reduce output noise).

Heavy Miller overcompensation on the 16-pin package can degrade AC PSRR. A large capacitor between pins 15 and 16 couples transients on the positive supply to the output buffer. Since the amplifier bandwidth is severely rolled off it cannot keep the output at the correct state at moderate frequencies. Hence, for good PSRR, either keep the Miller capacitance under 1000 pF or use the pin 15-to-ground compensation.

FIGURE 6. Overcompensation

	0.01 μF	90	90	2000*

*Also stable for $C_L \geq 0.05 \mu\text{F}$

Application Hints (Continued)

Because the LM363's output voltage is approximately one diode drop below the voltage at pin 15 (pin 8 for the 8-pin device), this point may be used to limit output swing as seen in *Figure 7a*. Current available from this pin is only 50 μA , so that zeners must have a sharp breakdown to clamp accurately. Alternatively, a diode tied to a voltage source could be used as in *Figure 7b*.

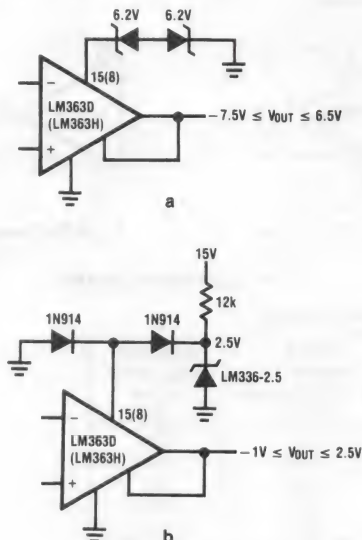

FIGURE 7. Output Clamp

TL/H/5609-15

SHIELD DRIVERS

When differential signals are sent through long cables, three problems occur. First, noise, both common-mode and differential, is picked up. Second, signal bandwidth is reduced by the RC low-pass filter formed by the source impedance and the cable capacitance. Finally, when these RC time constants are not identical (unbalanced source impedance and/or unbalanced capacitance), AC common-mode rejection is degraded, amplifying both induced noise and "ground" noise. Either filtering at the amplifier inputs or slowing down the amplifier by overcompensating will indeed reduce the noise, but the price is slower response. The LM363's dual shield drivers can actually increase bandwidth while reducing noise.

The way this is done is by bootstrapping out shield capacitance. The shield drivers follow the input signal. Since both sides of the shield capacitance swing the same amount, it is effectively out of the circuit at frequencies of interest. Hence, the input signal is not rolled off and AC CMRR is not degraded (*Figure 8*). The LM363's shield drivers can handle capacitances (shield to center conductor) as high as 1000 pF with source resistances up to 100 k Ω .

For best results, identical shielded cables should be used for both signal inputs, although small mismatches in shield driver to ground capacitance (≤ 500 pF) do not cause problems. At certain low values of cable capacitance (50 pF–200 pF), high frequency oscillations can occur at high source resistance (≥ 10 k Ω). This is alleviated by adding

50 pF to ground at both shield driver outputs. Do not use only one shield driver for a single-ended signal as oscillations can result; shield driver to input capacitance must be roughly balanced ($\pm 30\%$). To further reduce noise pickup, the shielded signal lines may be enclosed together in a grounded shield. If a large amount of RF noise is the problem, the only sure cure is a filter capacitor at both inputs; otherwise the RFI may be internally rectified, producing an offset.

DC loading on the shield drivers should be minimized. The drivers can only source approximately 40 μA ; above this value the input stage bias voltages change, degrading V_{OS} and CMRR. While the shield drivers can sink several mA, V_{OS} may degrade severely at loads above 100 μA (see Shield Driver Loading Error curve in Typical Performance Characteristics). Because the shield drivers are one diode drop above the input levels, unbalanced leakage paths from shield to input can produce an input offset at high source impedances. Buffering with emitter-followers (*Figure 8b*) reduces this leakage current by reducing the voltage differential and eliminates any loading on the amplifier.

b. NPN Followers to Reduce Offsets

TL/H/5609-16

FIGURE 8. Driving Shielded Cables

MISCELLANEOUS TRIMMING

The V_{OS} adjust and shield driver pins available on the 16-pin package may be used to trim the other parameters besides offset voltage, as illustrated in *Figure 10*. The bias-current trim relies on the fact that the voltage on the shield driver and gain setting pins is one diode drop respectively above and below the input voltage. Input bias current can be held to within 100 pA over the entire common-mode range, and input offset current always stays under 30 pA. The CMRR trims use the shield driver pins to drive the V_{OS} adjust pins, thus maintaining the LM363's ultra-high input impedance.

Application Hints (Continued)

If power supply rejection is critical, frequently only the negative PSRR need be adjusted, since the positive PSRR is more tightly specified. Any or all of the trim schemes of *Figure 10* can be combined as desired. As long as the center tap of the 100k trimpot is returned to a voltage 200 mV below V^+ , the trim schemes shown will not greatly affect

V_{OS} . Both the gain and DC CMRR trims can degrade positive PSRR; the positive PSRR can then be nulled out if desired. The correct order of trimming from first to last is bias current, gain, CMRR, negative PSRR, positive PSRR and V_{OS} .

Typical Applications

4 mA-20 mA Two Wire Current Transmitter

TL/H/5609-20

The LM329 reference provides excellent line regulation and gain stability. When bridge is balanced ($I_{OUT} = 4$ mA), there's no drop across R3 and R4, so that gain and offset adjustments are non-interactive. The LM334 configured as a zero-TC current source supplies quiescent current to circuit. R11 provides current limiting.

Design Equations

$$I_{OS} = (I_{R6} + I_{R7}) \left(1 + \frac{R_2}{R_1} \right) = 4 \text{ mA}$$

$$\text{Gain} = \frac{\Delta I_{OUT}}{\Delta V_{IN}} = \frac{A_V}{R_1} \times \frac{R_2 + R_3 + R_4}{R_3 + R_4} \approx \frac{10 \text{ mA}}{\text{mV}}$$

when $A_V = \text{LM363 voltage gain}$

$$\text{Pick } I_{334} = \frac{0.68 \text{ V}}{R_9} + \frac{68 \text{ mV}}{R_{10}} \approx 3.8 \text{ mA}$$

$$I_{MAX} = I_{334} + \frac{V_Z - 2.4 \text{ V}}{R_{11}} = 26 \text{ mA}$$

$$I_{BRIDGE(MAX)} \approx I_{334} - I_{363} \approx 1.5 \text{ mA}$$

Precision Op Amp

$$\begin{aligned} R_1 &= R_2 \\ I_{OUT} &= \frac{V_{IN}}{G R_1} \end{aligned}$$

Curvature Corrected Platinum RTD Thermometer

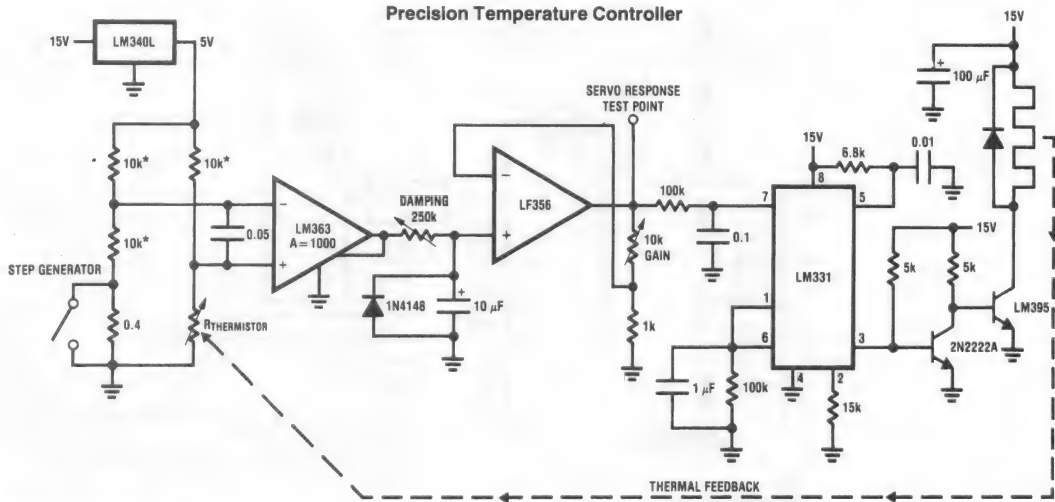

TL/H/5609-23

This thermometer is capable of 0.01°C accuracy over -50°C to +150°C. A unique trim arrangement eliminates cumbersome trim interactions so that zero, gain, and nonlinearity correction can be trimmed in one oven trip. Extra op amps provide full Kelvin sensing on the sensor without adding drift and offset terms found in other designs. A2 is configured as a Howland current pump, biasing the sensor with a fixed current.

Resistors R2, R3, R4 and R5 from a bridge driven into balance by A1. In balance, both inputs of A1 are at the same voltage. Since R6 = R7, A1 draws equal currents from both legs of the bridge. Any loading of the R4/R5 leg by the sensor would unbalance the bridge; therefore, both bridge taps are given to the sensor open circuit voltage and no current is drawn.

Surface Mount

Section 6 Contents

Surface Mount	6-3
---------------------	-----

Surface Mount

Cost pressures today are forcing many electronics manufacturers to automate their production lines. Surface mount technology plays a key role in this cost-savings trend because:

1. The mounting of devices on the PC board surface eliminates the expense of drilling holes;
2. The use of pick-and-place machines to assemble the PC boards greatly reduces labor costs;
3. The lighter and more compact assembled products resulting from the smaller dimensions of surface mount packages mean lower material costs.

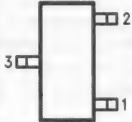

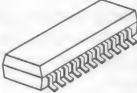

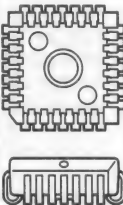

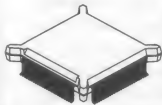

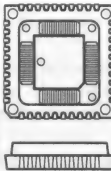

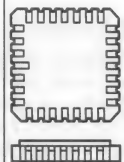

Production processes now permit both surface mount and insertion mount components to be assembled on the same PC board.

SURFACE MOUNT PACKAGING AT NATIONAL

To help our customers take advantage of this new technology, National has developed a line of surface mount packages. Ranging in lead counts from 3 to 360, the package offerings are summarized in Table I.

Lead center spacing keeps shrinking with each new generation of surface mount package. Traditional packages (e.g., DIPs) have a 100 mil lead center spacing. Surface mount packages currently in production (e.g., SOT, SOIC, PCC, LCC, LDCC) have a 50 mil lead center spacing. Surface mount packages in production release (e.g., PQFP) have a 25 mil lead center spacing. Surface mount packages in development (e.g., TAPEPAK™) will have a lead center spacing of only 12–20 mils.

TABLE I. Surface Mount Packages from National

Package Type	Small Outline Transistor (SOT)	Small Outline IC (SOIC)	Plastic Chip Carrier (PCC)	Plastic Quad Flat Pack (PQFP)	TAPEPAK™ (TP)	Leadless Chip Carrier (LCC) (LDCC)	Leaded Chip Carrier

*In production (or planned) for linear products.

LINEAR PRODUCTS IN SURFACE MOUNT

Linear functions available in surface mount include:

- Op amps
- Comparators
- Regulators
- References
- Data conversion
- Industrial
- Consumer
- Automotive

A complete list of linear part numbers in surface mount is presented in Table III. Refer to the datasheet in the appropriate chapter of this databook for a complete description of the device. In addition, National is continually expanding the list of devices offered in surface mount. If the functions you need do not appear in Table III, contact the sales office or distributor branch nearest you for additional information.

Automated manufacturers can improve their cost savings by using Tape-and-Reel for surface mount devices. Simplified handling results because hundreds-to-thousands of semiconductors are carried on a single Tape-and-Reel pack (see ordering and shipping information—printed later in this section—for a comparison of devices/reel vs. devices/rail for those surface mount package types being used for linear products). With this higher device count per reel (when compared with less than a 100 devices per rail), pick-and-place machines have to be re-loaded less frequently and lower labor costs result.

With Tape-and-Reel, manufacturers save twice—once from using surface mount technology for automated PC board assembly and again from less device handling during shipment and machine set-up.

BOARD CONVERSION

Besides new designs, many manufacturers are converting existing printed circuit board designs to surface mount. The resulting PCB will be smaller, lighter and less expensive to manufacture; but there is one caveat—be careful about the thermal dissipation capability of the surface mount package.

Because the surface mount package is smaller than the traditional dual-in-line package, the surface mount package is not capable of conducting as much heat away as the DIP (i.e., the surface mount package has a higher thermal resistance—see Table II).

The silicon for most National devices can operate up to a 150°C junction temperature (check the datasheet for the rare exception). Like the DIP, the surface mount package can actually withstand an ambient temperature of up to 125°C (although a commercial temperature range device will only be specified for a max ambient temperature of 70°C and an industrial temperature range device will only be specified for a max ambient temperature of 85°C). See AN-336, "Understanding Integrated Circuit Package Power Capabilities", (reprinted in the appendix of each linear databook volume) for more information.

TABLE II: Surface Mount Package Thermal Resistance Range*

Package	Thermal Resistance** (θ_{JA} , °C/W)
SO-8	120–175
SO-14	100–140
SO-14 Wide	70–110
SO-16	90–130
SO-16 Wide	70–100
SO-20	60–90
SO-24	55–85
PCC-20	70–100
PCC-28	60–90
PCC-44	40–60

*Actual thermal resistance for a particular device depends on die size. Refer to the datasheet for the actual θ_{JA} value.

**Test conditions: PCB mount (FR4 material), still air (room temperature), copper traces (150 × 20 × 10 mils).

Given a max junction temperature of 150°C and a maximum allowed ambient temperature, the surface mount device will be able to dissipate less power than the DIP device. This factor must be taken into account for new designs.

For board conversion, the DIP and surface mount devices would have to dissipate the same power. This means the surface mount circuit would have a lower maximum allowable ambient temperature than the DIP circuit. For DIP circuits where the maximum ambient temperature required is substantially lower than the maximum ambient temperature allowed, there may be enough margin for safe operation of the surface mount circuit with its lower maximum allowable ambient temperature. But where the maximum ambient temperature required of the DIP current is close to the maximum allowable ambient temperature, the lower maximum ambient temperature allowed for the surface mount circuit may fall below the maximum ambient temperature required. The circuit designer must be aware of this potential pitfall so that an appropriate work-around can be found to keep the surface mount package from being thermally overstressed in the application.

SURFACE MOUNT LITERATURE

National has published extensive literature on the subject of surface mount packaging. Engineers from packaging, quality, reliability, and surface mount applications have pooled their experience to provide you with practical hands-on knowledge about the construction and use of surface mount packages.

The applications note AN-450 "Surface Mounting Methods and their Effect on Product Reliability" is referenced on each SMD datasheet. In addition, "Wave Soldering of Surface Mount Components" is reprinted in this section for your information.

A FINAL WORD

National is a world leader in the design and manufacture of surface mount components.

Because of design innovations such as perforated copper leadframes, our small outline package is as reliable as our DIP—the laws of physics would have meant that a straight “junior copy” of the DIP would have resulted in an “S.O.” package of lower reliability. You benefit from this equivalence of reliability. In addition, our ongoing vigilance at each step of the production process assures that the reliability we designed in stays in so that only devices of the highest quality and reliability are shipped to your factory.

Our surface mount applications lab at our headquarters site in Santa Clara, California continues to research (and publish) methods to make it even easier for you to use surface mount technology. Your problems are our problems.

When you think “Surface Mount”—think “National”!

Ordering and Shipping Information

When you order a surface mount semiconductor, it will be in one of the several available surface mount package types. Specifying the Tape-and-Reel method of shipment means that you will receive your devices in the following quantities per Tape-and-Reel pack: SMD devices can also be supplied in conventional conductive rails.

Package	Package Designator	Max/Rail	Per Reel*
SO-8	M	100	2500
SO-14	M	50	2500
SO-14 Wide	WM	50	1000
SO-16	M	50	2500
SO-16 Wide	WM	50	1000
SO-20	M	40	1000
SO-24	M	30	1000
PCL-20	V	50	1000
PCL-28	V	40	1000
PCL-44	V	25	500
PQFP-196	VF	TBD	—
TP-40	TP	100	TBD
LCC-20	E	50	—
LCC-44	E	25	—

*Incremental ordering quantities. (National Semiconductor reserves the right to provide a smaller quantity of devices per Tape-and-Reel pack to preserve lot or date code integrity. See example below.)

Example: You order 5,000 LM324M ICs shipped in Tape-and-Reel.

- Case 1: All 5,000 devices have the same date code
 - You receive 2 SO-14 (Narrow) Tape-and-Reel packs, each having 2500 LM324M ICs
- Case 2: 3,000 devices have date code A and 2,000 devices have date code B
 - You receive 3 SO-14 (Narrow) Tape-and-Reel packs as follows:
 - Pack #1 has 2,500 LM324M ICs with date code A
 - Pack #2 has 500 LM324M ICs with date code A
 - Pack #3 has 2,000 LM324M ICs with date code B

Wave Soldering of Surface Mount Components

ABSTRACT

In facing the upcoming surge of "surface mount technology", many manufacturers of printed circuit boards have taken steps to convert some portions of their boards to this new process. However, as the availability of surface mount components is still limited, may have taken to mixing the lead-inserted standard dual-in-line packages (DIPs) with the surface mounted devices (SMDs). Furthermore, to take advantage of using both sides of the board, surface-mounted components are generally adhered to the bottom side of the board while the top side is reserved for the conventional lead-inserted packages. If processed through a wave solder machine, the semiconductor components are now subjected to extra thermal stresses (now that the components are totally immersed into the molten solder).

A discussion of the effect of wave soldering on the reliability of plastic semiconductor packages follows. This is intended to highlight the limitations which should be understood in the use of wave soldering of surface mounted components.

ROLE OF WAVE-SOLDERING IN APPLICATION OF SMDs

The generally acceptable methods of soldering SMDs are vapor phase reflow soldering and IR reflow soldering, both requiring application of solder paste on PW boards prior to placement of the components. However, sentiment still exists for retaining the use of the old wave-soldering machine.

Wave Soldering of Surface Mount Components (Continued)

The reasons being:

- 1) Most PC Board Assembly houses already possess wave soldering equipment. Switching to another technology such as vapor phase soldering requires substantial investment in equipment and people.
- 2) Due to the limited number of devices that are surface mount components, it is necessary to mix both lead inserted components and surface mount components on the same board.
- 3) Some components such as relays and switches are made of materials which would not be able to survive the temperature exposure in a vapor phase or IR furnace.

PW BOARD ASSEMBLY PROCEDURES

There are two considerations in which through-hole ICs may be combined with surface mount components on the PW Board:

- a) Whether to mount ICs on one or both sides of the board.
- b) The sequence of soldering using Vapor Phase, IR or Wave Soldering singly or combination of two or more methods.

The various processes that may be employed are:

A) Wave Solder before Vapor/IR reflow solder.

1. Components on the same side of PW Board.
Lead insert standard DIPs onto PW Board Wave solder (conventional)
Wash and lead trim
Dispense solder paste on SMD pads
Pick and place SMDs onto PW Board
Bake
Vapor phase/IR reflow
Clean
2. Components on opposite side of PW Board.
Lead insert standard DIPs onto PW Board
Wave Solder (conventional)
Clean and lead trim
Invert PW Board
Dispense solder paste on SMD pads
Dispense drop of adhesive on SMD sites (optional for smaller components)
Pick and place SMDs onto board
Bake/Cure
Invert board to rest on raised fixture
Vapor/IR reflow soldering
Clean

B) Vapor/IR reflow solder then Wave Solder.

1. Components on the same side of PW Board.
Solder paste screened on SMD side of Printed Wire Board
Pick and place SMDs
Bake
Vapor/IR reflow
Lead insert on same side as SMDs
Wave solder
Clean and trim underside of PCB

C) Vapor/IR reflow only.

1. Components on the same side of PW Board.
Trim and form standard DIPs in "gull wing" configuration
Solder paste screened on PW Board
Pick and place SMDs and DIPs
Bake
Vapor/IR reflow
Clean
2. Components on opposite sides of PW Board.
Solder paste screened on SMD-side of Printed Wire Board
Adhesive dispensed at central location of each component
Pick and place SMDs
Bake
Solder paste screened on all pads on DIP-side or alternatively apply solder rings (performs) on leads
Lead insert DIPs
Vapor/IR reflow
Clean and lead trim

D) Wave Soldering Only

1. Components on opposite sides of PW Board.
Adhesive dispense on SMD side of PW Board
Pick and place SMDs
Cure adhesive
Lead insert top side with DIPs
Wave solder with SMDs down and into solder bath
Clean and lead trim

All of the above assembly procedures can be divided into three categories for I.C. Reliability considerations:

- 1) Components are subjected to both a vapor phase/IR heat cycle then followed by a wave-solder heat cycle or vice versa.
- 2) Components are subjected to only a vapor phase/IR heat cycle.
- 3) Components are subjected to wave-soldering only and SMDs are subjected to heat by immersion into a solder pot.

Of these three categories, the last is the most severe regarding heat treatment to a semiconductor device. However, note that semiconductor molded packages generally possess a coating of solder on their leads as a final finish for solderability and protection of base leadframe material. Most semiconductor manufacturers solder-plate the component leads, while others perform hot solder dip. In the latter case the packages may be subjected to total immersion into a hot solder bath under controlled conditions (manual operation) or be partially immersed while in a 'pallet' where automatic wave or DIP soldering processes are used. It is, therefore, possible to subject SMDs to solder heat under certain conditions and not cause catastrophic failures.

Wave Soldering of Surface Mount Components (Continued)

THERMAL CHARACTERISTICS OF MOLDED INTEGRATED CIRCUITS

Since Plastic DIPs and SMDs are encapsulated with a thermoset epoxy, the thermal characteristics of the material generally correspond to a TMA (Thermo-Mechanical Analysis) graph. The critical parameters are (a) its Linear thermal expansion characteristics and (b) its glass transition temperature after the epoxy has been fully cured. A typical TMA graph is illustrated in Figure 1. Note that the epoxy changes to a higher thermal expansion once it is subjected to temperatures exceeding its glass transition temperature. Metals (as used on lead frames, for example) do not have this characteristic and generally will have a consistent Linear thermal expansion over the same temperature range.

In any good reliable plastic package, the choice of lead frame material should be such to match its thermal expansion properties to that of the encapsulating epoxy. In the event that there is a mismatch between the two, stresses can build up at the interface of the epoxy and metal. There now exists a tendency for the epoxy to separate from the metal lead frame in a manner similar to that observed on bimetallic thermal range.

In most cases when the packages are kept at temperatures below their glass transition, there is a small possibility of separation at the epoxy-metal interface. However, if the package is subjected to temperature above its glass-transition temperature, the epoxy will begin to expand much faster than the metal and the probability of separation is greatly increased.

CONVENTIONAL WAVE-SOLDERING

Most wave-soldering operations occur at temperatures between 240–260°C. Conventional epoxies for encapsulation have glass-transition temperature between 140–170°C. An I.C. directly exposed to these temperatures risks its long term functionality due to epoxy/metal separation.

Fortunately, there are factors that can reduce that element of risk:

- 1) The PW board has a certain amount of heat-sink effect and tends to shield the components from the temperature of the solder (if they were placed on the top side of the board). In actual measurements, DIPs achieve a temperature between 120–150°C in a 5-second pass over the solder. This accounts for the fact that DIPs mounted in the conventional manner are reliable.
- 2) In conventional soldering, only the tip of each lead in a DIP would experience the solder temperature because the epoxy and die are standing above the PW board and out of the solder bath.

EFFECT ON PACKAGE PERFORMANCE BY EPOXY-METAL SEPARATION

In wave soldering, it is necessary to use fluxes to assist the solderability of the components and PW boards. Some facilities may even process the boards and components through some form of acid cleaning prior to the soldering temperature. If separation occurs, the flux residues and acid residues (which may be present owing to inadequate cleaning) will be forced into the package mainly by capillary action as the residues move away from the solder heat source. Once the package is cooled, these contaminants are now trapped within the package and are available to diffuse with moisture from the epoxy over time. It should be noted that electrical tests performed immediately after soldering generally will give no indication of this potential problem. In any case, the end result will be corrosion of the chip metallization over time and premature failure of the device in the field.

VAPOR PHASE/IR REFLOW SOLDERING

In both vapor phase and IR reflow soldering, the risk of separation between epoxy/metal can also be high. Operating temperatures are 215°C (vapor phase) or 240°C (IR) and duration may also be longer (30 sec–60 sec). On the same theoretical basis, there should also be separation. However, in both these methods, solder paste is applied to the pads of the boards; no fluxes are used. Also, the devices are not immersed into the hot solder. This reduces the possibility of solder forcing itself into the epoxy-lead frame interface. Furthermore, in the vapor phase system, the soldering environment is "oxygen-free" and considered "contaminant free". Being so, it could be visualized that as far as reliability with respect to corrosion, both of these methods are advantageous over wave soldering.

BIAS MOISTURE TEST

A bias moisture test was designed to determine the effect on package performance. In this test, the packages are pressured in a stream chamber to accelerate penetration of moisture into the package. An electrical bias is applied on the device. Should there be any contaminants trapped within the package, the moisture will quickly form an electrolyte and cause the electrodes (which are the lead fingers), the gold wire and the aluminum bond-pads of the silicon device to corrode. The aluminum bond-pads, being the weakest link of the system, will generally be the first to fail.

This proprietary accelerated bias/moisture pressure-test is significant in relation to the life test condition at 85°C and

FIGURE 1. Thermal Expansion and Glass Transition Temperature

TL/XX/0026-12

Wave Soldering of Surface Mount Components (Continued)

85% relative humidity. Once cycle of approximately 100 hours has been shown to be equivalent to 2000 hours in the 85/85 condition. Should the packages start to fail within the first cycle in the test, it is anticipated that the boards with these components in the harsh operating environment (85°C/85% RH) will experience corrosion and eventual electrical failures within its first 2000 hours of operation.

Whether this is significant to a circuit board manufacturer will obviously be dependent on the products being manufactured and the workmanship or reliability standards. Generally in systems with a long warranty and containing many components, it is advisable both on a reputation and cost basis to have the most reliable parts available.

TEST RESULTS

The comparison of vapor phase and wave-soldering upon the reliability of molded Small-Outline packages was performed using the bias moisture test (see Table IV). It is clearly seen that vapor phase reflow soldering gave more consistent results. Wave-soldering results were based on manual operation giving variations in soldering parameters such as temperature and duration.

TABLE IV. Vapor Phase vs. Wave Solder

1. Vapor phase (60 sec. exposure @ 215°C)
= 9 failures/1723 samples
= 0.5% (average over 32 sample lots)
 2. Wave solder (2 sec total immersion @ 260°C)
= 16 failures/1201 samples
= 1.3% (average over 27 sample lots)
- Package: SO-14 lead
Test: Bias moisture test 85% R.H.,
85°C for 2000 hours
Device: LM324M

In Table V we examine the tolerance of the Small-Outlined (SOIC) package to varying immersion time in a hot solder pot. SO-14 lead molded packages were subjected to the bias moisture test after being treated to the various soldering conditions and repeated four (4) times. End point was an electrical test after an equivalent of 4000 hours 85/85 test. Results were compared for packages by itself against packages which were surface-mounted onto a FR-4 printed wire board.

**TABLE V. Summary of Wave Solder Results
(85% R.H./85°C Bias Moisture Test, 2000 hours)
(# Failures/Total Tested)**

	Unmounted	Mounted
Control/Vapor Phase 15 sec @ 215°C	0/114	0/84
Solder Dip 2 sec @ 260°C	2/144 (1.4%)	0/85
Solder Dip 4 sec @ 260°C	—	0/83
Solder Dip 6 sec @ 260°C	13/248 (5.2%)	1/76 (1.3%)
Solder Dip 10 sec @ 260°C	14/127 (11.0%)	3/79 (3.8%)
Package: SO-14 lead		
Device: LM324M		

Since the package is of very small mass and experiences a rather sharp thermal shock followed by stresses created by the mismatch in expansion, the results show the package being susceptible to failures after being immersed in excess of 6 seconds in a solder pot. In the second case where the packages were mounted, the effect of severe temperature excursion was reduced. In the second case where the packages were mounted, the effect of severe temperature excursion was reduced. In any case, because of the repeated treatment, the package had failures when subjected in excess of 6 seconds immersion in hot solder. The safety margin is therefore recommended as maximum 4 seconds immersion. If packages were immersed longer than 4 seconds, there is a probable chance of finding some long term reliability failures even though the immediate electrical test data could be acceptable.

Finally, Table VI examines the bias moisture test performed on surface mount (SOIC) components manufactured by various semiconductor houses. End point was an electrical test after an equivalent of 6000 hours in a 85/85 test. Failures were analyzed and corrosion was checked for in each case to detect flaws in package integrity.

**TABLE VI. U.S. Manufacturers Integrated Circuits
Reliability In Various Solder Environments

SUMMARY

Based on the results presented, it is noted that surface-mounted components are as reliable as standard molded DIP packages. Whereas DIPs were never processed by being totally immersed in a hot solder wave during printed circuit board soldering, surface mounted components such as SOICs (Small Outline) are expected to survive a total immersion in the hot solder in order to capitalize on maximum population on boards. Being constructed from a thermoset plastic of relatively low Tg compared to the soldering temperature, the ability of the package to survive is dependent on the time of immersion and also the cleanliness of material. The results indicate that one should limit the immersion time of package in the solder wave to a maximum of 4 seconds in order to truly duplicate the reliability of a DIP. As the package size is reduced, as in a SO-8 lead, the requirement becomes even more critical. This is shown by the various manufacturers' performance. Results indicate there is room for improvement since not all survived the hot solder immersion without compromise to lower reliability.

Small Outline (SO) Package Surface Mounting Methods—Parameters and Their Effect on Product Reliability

The SO (small outline) package has been developed to meet customer demand for ever-increasing miniaturization and component density.

COMPONENT SIZE COMPARISON

Because of its small size, reliability of the product assembled in SO packages needs to be carefully evaluated.

SO packages at National were internally qualified for production under the condition that they be of comparable reliability performance to a standard dual in line package under all accelerated environmental tests. Figure A is a summary of accelerated bias moisture test performance on 30V bipolar and 15V CMOS product assembled in SO and DIP (control) packages.

FIGURE A

TL/XX/0026-15

In order to achieve reliability performance comparable to DIPs—SO packages are designed and built with materials and processes that effectively compensate for their small size.

All SO packages tested on 85%RA, 85°C were assembled on PC conversion boards using vapor-phase reflow soldering. With this approach we are able to measure the effect of surface mounting methods on reliability of the process. As illustrated in Figure A no significant difference was detected between the long term reliability performance of surface mounted S.O. packages and the DIP control product for up to 6000 hours of accelerated 85%/85°C testing.

SURFACE-MOUNT PROCESS FLOW

The standard process flowcharts for basic surface-mount operation and mixed-lead insertion/surface-mount operations, are illustrated on the following pages.

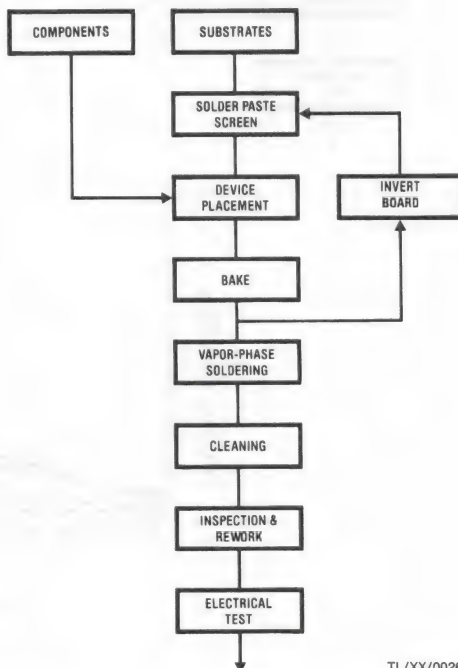

Usual variations encountered by users of SO packages are:

- Single-sided boards, surface-mounted components only.
- Single-sided boards, mixed-lead inserted and surface-mounted components.
- Double-sided boards, surface-mounted components only.
- Double-sided boards, mixed-lead inserted and surface-mounted components.

In consideration of these variations, it became necessary for users to utilize techniques involving wave soldering and adhesive applications, along with the commonly-used vapor-phase solder reflow soldering technique.

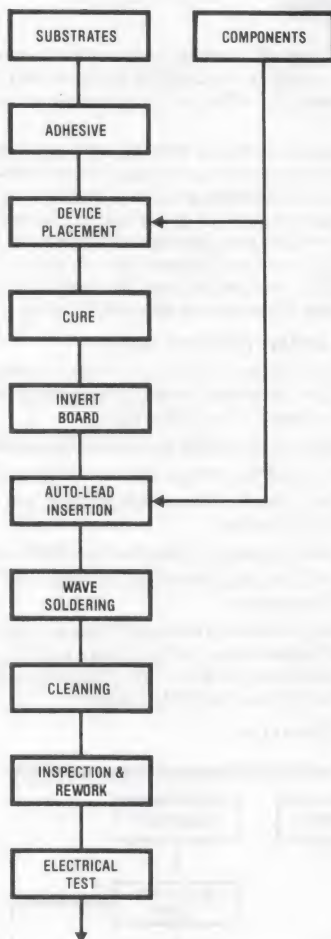

PRODUCTION FLOW

Basic Surface-Mount Production Flow

TL/XX/0026-16

Mixed Surface-Mount and Axial-Leaded Insertion Components Production Flow

TL/XX/0026-17

Thermal stress of the packages during surface-mounting processing is more severe than during standard DIP PC board mounting processes. *Figure B* illustrates package temperature versus wave soldering dwell time for surface mounted packages (components are immersed into the molten solder) and the standard DIP wave soldering process. (Only leads of the package are immersed into the molten solder).

TL/XX/0026-18

FIGURE B

For an ideal package, the thermal expansion rate of the encapsulant should match that of the leadframe material in order for the package to maintain mechanical integrity during the soldering process. Unfortunately, a perfect matchup of thermal expansion rates with most presently used packaging materials is scarce. The problem lies primarily with the epoxy compound.

Normally, thermal expansion rates for epoxy encapsulant and metal lead frame materials are linear and remain fairly close at temperatures approaching 160°C, *Figure C*. At lower temperatures the difference in expansion rate of the two materials is not great enough to cause interface separation. However, when the package reaches the glass-transition temperature (T_g) of epoxy (typically 160–165°C), the thermal expansion rate of the encapsulant increases sharply, and the material undergoes a transition into a plastic state. The epoxy begins to expand at a rate three times or more greater than the metal leadframe, causing a separation at the interface.

FIGURE C

TL/XX/0026-19

When this happens during a conventional wave soldering process using flux and acid cleaners, process residues and even solder can enter the cavity created by the separation and become entrapped when the material cools. These contaminants can eventually diffuse into the interior of the package, especially in the presence of moisture. The result is die contamination, excessive leakage, and even catastrophic failure. Unfortunately, electrical tests performed immediately following soldering may not detect potential flaws.

Most soldering processes involve temperatures ranging up to 260°C, which far exceeds the glass-transition temperature of epoxy. Clearly, circuit boards containing SMD packages require tighter process controls than those used for boards populated solely by DIPs.

Figure D is a summary of accelerated bias moisture test performance on the 30V bipolar process.

4 — dwell time 4 seconds

5 — dwell time 6 seconds

6 — dwell time 10 seconds

TL/XX/0026-20

FIGURE D

It is clear based on the data presented that SO packages soldered onto PC boards with the vapor phase reflow process have the best long term bias moisture performance and this is comparable to the performance of standard DIP packages. The key advantage of reflow soldering methods is the clean environment that minimized the potential for contamination of surface mounted packages, and is preferred for the surface-mount process.

When wave soldering is used to surface mount components on the board, the dwell time of the component under molten solder should be no more than 4 seconds, preferably under 2 seconds in order to prevent damage to the component. Non-Halide, or (organic acid) fluxes are highly recommended.

PICK AND PLACE

The choice of automatic (all generally programmable) pick-and-place machines to handle surface mounting has grown considerably, and their selection is based on individual needs and degree of sophistication.

The basic component-placement systems available are classified as:

(a) In-line placement

- Fixed placement stations
- Boards indexed under head and respective components placed

(b) Sequential placement

- Either a X-Y moving table system or a θ , X-Y moving pickup system used
- Individual components picked and placed onto boards

(c) Simultaneous placement

- Multiple pickup heads
- Whole array of components placed onto the PCB at the same time

(d) Sequential/simultaneous placement

- X-Y moving table, multiple pickup heads system
- Components placed on PCB by successive or simultaneous actuation of pickup heads

The SO package is treated almost the same as surface-mount, passive components requiring correct orientation in placement on the board.

Pick and Place Action

TL/XX/0026-21

BAKE

This is recommended, despite claims made by some solder paste suppliers that this step be omitted.

The functions of this step are:

- Holds down the solder globules during subsequent reflow soldering process and prevents expulsion of small solder balls.
- Acts as an adhesive to hold the components in place during handling between placement to reflow soldering.
- Holds components in position when a double-sided surface-mounted board is held upside down going into a vapor-phase reflow soldering operation.
- Removes solvents which might otherwise contaminate other equipment.
- Initiates activator cleaning of surfaces to be soldered.
- Prevents moisture absorption.

The process is moreover very simple. The usual schedule is about 20 minutes in a 65°C–95°C (dependent on solvent system of solder paste) oven with adequate venting. Longer bake time is not recommended due to the following reasons:

- The flux will degrade and affect the characteristics of the paste.
- Solder globules will begin to oxidize and cause solderability problems.
- The paste will creep and after reflow, may leave behind residues between traces which are difficult to remove and vulnerable to electro-migration problems.

REFLOW SOLDERING

There are various methods for reflowing the solder paste, namely:

- Hot air reflow
- Infrared heating (furnaces)
- Convectional oven heating
- Vapor-phase reflow soldering
- Laser soldering

For SO applications, hot air reflow/infrared furnace may be used for low-volume production or prototype work, but vapor-phase soldering reflow is more efficient for consistency and speed. Oven heating is not recommended because of "hot spots" in the oven and uneven melting may result. Laser soldering is more for specialized applications and requires a great amount of investment.

HOT GAS REFLOW/INFRARED HEATING

A hand-held or table-mount air blower (with appropriate orifice mask) can be used.

The boards are preheated to about 100°C and then subjected to an air jet at about 260°C. This is a slow process and results may be inconsistent due to various heat-sink properties of passive components.

Use of an infrared furnace is the next step to automating the concept, except that the heating is promoted by use of IR lamps or panels. The main objection to this method is that certain materials may heat up at different rates under IR radiation and may result in damage to these components (usually sockets and connectors). This could be minimized by using far-infrared (non-focused) system.

VAPOR-PHASE REFLOW SOLDERING

Currently the most popular and consistent method, vapor-phase soldering utilizes a fluoroinert fluid with excellent heat-transfer properties to heat up components until the solder paste reflows. The maximum temperature is limited by the vapor temperature of the fluid.

The commonly used fluids (supplied by 3M Corp) are:

- FC-70, 215°C vapor (most applications) or FX-38
- FC-71, 253°C vapor (low-lead or tin-plate)

HTC, Concord, CA, manufactures equipment that utilizes this technique, with two options:

- Batch systems, where boards are lowered in a basket and subjected to the vapor from a tank of boiling fluid.
- In-line conveyORIZED systems, where boards are placed onto a continuous belt which transports them into a concealed tank where they are subjected to an environment of hot vapor.

Dwell time in the vapor is generally on the order of 15–30 seconds (depending on the mass of the boards and the loading density of boards on the belt).

In-Line Conveyorized Vapor-Phase Soldering

The question of thermal shock is asked frequently because of the relatively sharp increase in component temperature from room temperature to 215°C. SO packages mounted on representative boards have been tested and have shown little effect on the integrity of the packages. Various packages, such as cerdips, metal cans and TO-5 cans with glass seals, have also been tested.

TL/XX/0026-25

Solder Joints on a SO-14 Package on PCB

TL/XX/0026-26

PRINTED CIRCUIT BOARD

The SO package is molded out of clean, thermoset plastic compound and has no particular compatibility problems with most printed circuit board substrates.

The package can be reliably mounted onto substrates such as:

- G10 or FR4 glass/resin
- FR5 glass/resin systems for high-temperature applications
- Polyimide boards, also high-temperature applications
- Ceramic substrates

General requirements for printed circuit boards are:

- Mounting pads should be solder-plated whenever applicable.
- Solder masks are commonly used to prevent solder bridging of fine lines during soldering.
- The mask also protects circuits from processing chemical contamination and corrosion.

If coated over pre-tinned traces, residues may accumulate at the mask/trace interface during subsequent reflow, leading to possible reliability failures.

Recommended application of solder resist on bare, clean traces prior to coating exposed areas with solder.

General requirements for solder mask:

- Good pattern resolution.
- Complete coverage of circuit lines and resistance to flaking during soldering.
- Adhesion should be excellent on substrate material to keep off moisture and chemicals.
- Compatible with soldering and cleaning requirements.

SOLDER PASTE SCREEN PRINTING

With the initial choice of printed circuit lithographic design and substrate material, the first step in surface mounting is the application of solder paste.

The typical lithographic "footprints" for SO packages are illustrated below. Note that the 0.050" lead center-center spacing is not easily managed by commercially-available air pressure, hand-held dispensers.

Using a stainless-steel, wire-mesh screen stencilled with an emulsion image of the substrate pads is by far the most common and well-tried method. The paste is forced through the screen by a V-shaped plastic squeegee in a sweeping manner onto the board placed beneath the screen.

The setup for SO packages has no special requirement from that required by other surface-mounted, passive components. Recommended working specifications are:

- Use stainless-steel, wire-mesh screens, #80 or #120, wire diameter 2.6 mils. Rule of thumb: mesh opening should be approximately 2.5–5 times larger than the average particle size of paste material.
- Use squeegee of Durometer 70.
- Experimentation with squeegee travel speed is recommended, if available on machine used.
- Use solder paste of mesh 200–325.
- Emulsion thickness of 0.005" usually used to achieve a solder paste thickness (wet) of about 0.008" typical.
- Mesh pattern should be 90 degrees, square grid.
- Snap-off height of screen should not exceed $\frac{1}{8}$ ", to avoid damage to screens and minimize distortion.

SOLDER PASTE

Selection of solder paste tends to be confusing, due to numerous formulations available from various manufacturers. In general, the following guidelines are sufficient to qualify a particular paste for production:

- Particle sizes (see photographs below). Mesh 325 (approximately 45 microns) should be used for general purposes, while larger (solder globules) particles are preferred for leadless components (LCC). The larger particles can easily be used for SO packages.

- Composition; generally 60/40 or 63/37 Sn/Pb. Use 62/36 Sn/Pb with 2% Ag in the presence of Au on the soldering area. This formulation reduces problems of metal leaching from soldering pads.
- RMA flux system usually used.
- Use paste with approximately 88–90% solids.

CLEANING

The most critical process in surface mounting SO packages is in the cleaning cycle. The package is mounted very close to the surface of the substrate and has a tendency to collect residue left behind after reflow soldering.

Important considerations in cleaning are:

- Time between soldering and cleaning to be as short as possible. Residue should not be allowed to solidify on the substrate for long periods of time, making it difficult to dislodge.
- A low surface tension solvent (high penetration) should be employed. Solvents commercially available are:

Freon TMS (general purpose)
Freon TE35/TP35 (cold-dip cleaning)
Freon TES (general purpose)

It should also be noted that these solvents generally will leave the substrate surface hydrophobic (moisture repellent), which is desirable.

Prelate or 1,1,1-Trichloroethane
Kester 5120/5121

- A defluxer system which allows the workpiece to be subjected to a solvent vapor, followed by a rinse in pure solvent and a high-pressure spray lance are the basic requirements for low-volume production.
- For volume production, a conveyorized, multiple hot solvent spray/jet system is recommended.
- Rosin, being a natural occurring material, is not readily soluble in solvents, and has long been a stumbling block to the cleaning process. In recent developments, synthetic flux (SA flux), which is readily soluble in Freon TMS solvent, has been developed. This should be explored where permissible.

The dangers of an inadequate cleaning cycle are:

- Ion contamination, where ionic residue left on boards would cause corrosion to metallic components, affecting the performance of the board.
- Electro-migration, where ionic residue and moisture present on electrically-biased boards would cause dendritic growth between close spacing traces on the substrate, resulting in failures (shorts).

REWORK

Should there be a need to replace a component or re-align a previously disturbed component, a hot air system with appropriate orifice masking to protect surrounding components may be used.

When rework is necessary in the field, specially-designed tweezers that thermally heat the component may be used to remove it from its site. The replacement can be fluxed at the

Hot-Air Rework Machine

TL/XX/0026-96

lead tips or, if necessary, solder paste can be dispensed onto the pads using a varimeter. After being placed into position, the solder is reflowed by a hot-air jet or even a standard soldering iron.

WAVE SOLDERING

In a case where lead insertions are made on the same board as surface-mounted components, there is a need to include a wave-soldering operation in the process flow.

Two options are used:

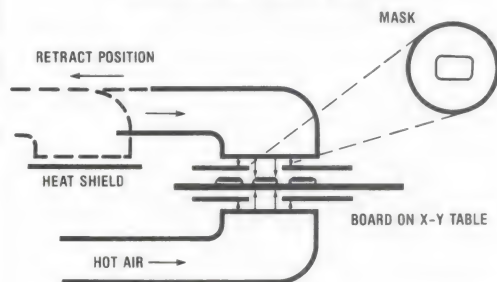

- Surface mounted components are placed and vapor phase reflowed before auto-insertion of remaining components. The board is carried over a standard wave-solder system and the underside of the board (only lead-inserted leads) soldered.
- Surface-mounted components are placed in position, but no solder paste is used. Instead, a drop of adhesive about 5 mils maximum in height with diameter not exceeding 25% width of the package is used to hold down the package. The adhesive is cured and then proceeded to auto-insertion on the reverse side of the board (surface-mounted side facing down). The assembly is then passed over a "dual wave" soldering system. Note that the surface-mounted components are immersed into the molten solder.

Lead trimming will pose a problem after soldering in the latter case, unless the leads of the insertion components are pre-trimmed or the board specially designed to localize certain areas for easy access to the trim blade.

The controls required for wave soldering are:

- Solder temperature to be 240–260°C. The dwell time of components under molten solder to be short (preferably kept under 2 seconds), to prevent damage to most components and semiconductor devices.
- RMA (Rosin Mildly Activated) flux or more aggressive OA (Organic Acid) flux are applied by either dipping or foam fluxing on boards prior to preheat and soldering. Cleaning procedures are also more difficult (aqueous, when OA flux is used), as the entire board has been treated by flux (unlike solder paste, which is more or less localized). Non-halide OA fluxes are highly recommended.
- Preheating of boards is essential to reduce thermal shock on components. Board should reach a temperature of about 100°C just before entering the solder wave.
- Due to the closer lead spacings (0.050" vs 0.100" for dual-in-line packages), bridging of traces by solder could occur. The reduced clearance between packages also causes "shadowing" of some areas, resulting in poor solder coverage. This is minimized by dual-wave solder systems.

Hot-Air Solder Rework Station

TL/XX/0026-35

Mixed Surface Mount and Lead Insertion

TL/XX/0026-37

A typical dual-wave system is illustrated below, showing the various stages employed. The first wave typically is in turbulence and given a transverse motion (across the motion of the board). This covers areas where "shadowing" occurs. A second wave (usually a broad wave) then proceeds to perform the standard soldering. The departing edge from the solder is such to reduce "icicles," and is still further reduced by an air knife placed close to the final soldering step. This air knife will blow off excess solder (still in the fluid stage) which would otherwise cause shorts (bridging) and solder bumps.

AQUEOUS CLEANING

- For volume production, a conveyORIZED system is often used with a heated recirculating spray wash (water temperature 130°C), a final spray rinse (water temperature 45–55°C), and a hot (120°C) air/air-knife drying section.
- For low-volume production, the above cleaning can be done manually, using several water rinses/tanks. Fast-drying solvents, like alcohols that are miscible with water, are sometimes used to help the drying process.
- Neutralizing agents which will react with the corrosive materials in the flux and produce material readily soluble in water may be used; the choice depends on the type of flux used.
- Final rinse water should be free from chemicals which are introduced to maintain the biological purity of the water. These materials, mostly chlorides, are detrimental to the assemblies cleaned because they introduce a fresh amount of ionizable material.

Dual Wave

TL/XX/0026-38

CONFORMAL COATING

Conformal coating is recommended for high-reliability PCBs to provide insulation resistance, as well as protection against contamination and degradation by moisture.

Requirements:

- Complete coating over components and solder joints.
- Thixotropic material which will not flow under the packages or fill voids, otherwise will introduce stress on solder joints on expansion.
- Compatibility and possess excellent adhesion with PCB material/components.
- Silicones are recommended where permissible in application.

SMD Lab Support

FUNCTIONS

Demonstration—Introduce first-time users to surface-mounting processes.

Service—Investigate problems experienced by users on surface mounting.

Reliability Builds—Assemble surface-mounted units for reliability data acquisition.

Techniques—Develop techniques for handling different materials and processes in surface mounting.

Equipment—In conjunction with equipment manufacturers, develop customized equipments to handle high density, new technology packages developed by National.

In-House Expertise—Availability of in-house expertise on semiconductor research/development to assist users on packaging queries.

Summary of Commercial Reliability Programs

General

National Semiconductor Commercial Reliability Programs provide a broad range of off-the-shelf enhanced semiconductor products that supply an extra measure of quality and reliability needed in high-stress or difficult to service applications.

National's A+ and B+ programs allow each individual customer to:

- Minimize the need for incoming electrical inspection
- Eliminate the need and associated costs of using independent testing laboratories
- Reduction in infant mortality rate
- Reduction in reworked board costs
- Reduction in warranty and service costs

A+ Product Enhancement

The A+ Product Enhancement incorporates the benefits of the Multiple-Pass and Elevated Temperature along with "BURN-IN."

The A+ Program provides:

- 100% Temperature Cycling
- 100% Electrical Testing at Room and High Temperature
- 100% Burn-In Testing Combining Increased Temperature with Applied Voltage
- Acceptable Quality Levels Greater than Industry Norm

Typical A+ Flow is:

- SEM
- Assembly and Seal
- Four Hour 150°C Bake
- Five Temperature Cycles (0°C to +100°C)
- High Temperature Electrical Test
- Electrical Test
- Burn-In (160 hours at a minimum junction temperature of 125°C)
- DC Parametric and Function Tests
- Tightened Quality Control Inspection Plans

Note: Certain products may follow slightly different process flows dictated by specific capabilities and device characteristics, consult NSC.

P+ Product Enhancement

The P+ product enhancement program applies to regulator devices and offers an added advantage. P+ involves a dynamic self-heating burn-in that tests the thermal shutdown of the regulator. P+ is proven more effective than the standard 125°C burn-in as an early screen for infant mortality defects. It sharply reduces the cost of testing incoming components. Reliability Report L-140 further explains the P+ process. The following chart lists regulators which receive P+ prior to shipment and at no additional cost.

Appendix D

Military Aerospace Programs from National Semiconductor

This appendix is intended to provide a brief overview of military products available from National Semiconductor. For further information, refer to our *1987 Reliability Handbook*.

MIL-M-38510

The MIL-M-38510 Program, which is sometimes called the JAN IC Program, is administered by the Defense Electronics Supply Center (DESC). The purpose of this program is to provide the military community with standardized products that have been manufactured and screened to government-controlled specifications in government-certified facilities. All 38510 manufacturers must be formally qualified and their products listed on DESC's Qualified Products List (QPL) before devices can be marked and shipped as JAN product.

There are two processing levels specified within MIL-M-38510: Classes S and B. Class S is typically specified for space flight applications, while Class B is used for aircraft and ground systems. National is a major supplier of both classes of devices. Screening requirements are outlined in Table III.

Tables I and II explain the JAN device marking system.

Copies of MIL-M-38510, the QPL, and other related documents may be obtained from:

Naval Publications and Forms Center
5801 Tabor Avenue
Philadelphia, PA 19120
(212) 697-2179

DESC Specifications

DESC specifications are issued to provide standardized versions of devices which are not yet available as JAN product. MIL-STD-883 Class B screening is coupled with tightly controlled electrical specifications which have been written to allow a manufacturer to use his standard electrical tests. A current listing of National's DESC specification offerings can be obtained from our franchised distributors, sales offices, or DESC. DESC is located in Dayton, Ohio.

MIL-STD-883

Although originally intended to establish uniform test methods and procedures, MIL-STD-883 has also become the general specification for non-JAN military product. Revision C of this document defines the minimum requirements for a device to be marked and advertised as 883-compliant. Included are design and construction criteria, documentation controls, electrical and mechanical screening requirements, and quality control procedures. Details can be found in paragraph 1.2.1 of MIL-STD-883.

National offers both 883 Class B and 883 Class S product. The screening requirements for both classes of product are outlined in Table III.

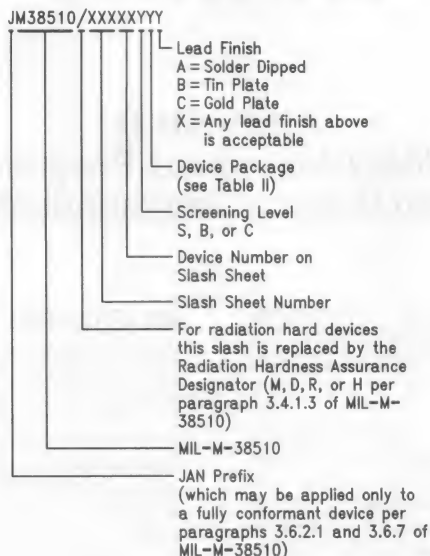

As with DESC specifications, a manufacturer is allowed to use his standard electrical tests provided that all critical parameters are tested. Also, the electrical test parameters, test conditions, test limits, and test temperatures must be clearly documented. At National Semiconductor, this information is available via our RETS (Reliability Electrical Test Specification Program). The RETS document is a complete description of the electrical tests performed and is controlled by our QA department. Individual copies are available upon request.

Some of National's older products are not completely compliant with MIL-STD-883 but are still required for use in military systems. These devices are screened to the same stringent requirements as 883 product but are marked "-MIL".

Military Screening Program (MSP)

National's Military Screening Program was developed to make screened versions of advanced products such as gate arrays and microprocessors available more quickly than is possible for JAN and 883 devices. Through this program, screened product is made available for prototypes and breadboards prior to or during the JAN or 883 qualification activities. MSP products receive the 100% screening of Table III but are not subjected to Group C and D quality conformance testing. Other criteria such as electrical testing and temperature range will vary depending upon individual device status and capability.

TABLE I. The MIL-M-38510 Part Marking

CI24-1

TABLE II. JAN Package Codes

38510 Package Designation	Microcircuit Industry Description
A	14-Pin 1/4" X 1/4" (metal) flat pack
B	14-Pin 3/16" X 1/4" flat pack
C	14-Pin 1/4" X 3/4" dual-in-line
D	14-Pin 1/4" X 3/8" (ceramic) flat pack
E	16-Pin 1/4" X 3/8" dual-in-line
F	16-Pin 1/4" X 3/8" (metal or ceramic) flat pack
G	8-pin TO-99 can or header
H	10-pin 1/4" x 1/4" (metal) flat pack
I	10-pin TO-100 can or header
J	24-pin 1/2" x 1-1/4" dual-in-line
K	24-pin 3/8" x 5/8" flat pack
L	24-pin 1/4" x 1-1/4" dual-in-line
M	12-pin TO-101 can or header
N	(Note 1)
P	8-pin 1/4" x 3/8" dual-in-line
Q	40-pin 3/16" x 2-1/16" dual-in-line
R	20-pin 1/4" x 1-1/16" dual-in-line
S	20-pin 1/4" x 1/2" flat pack
T	(Note 1)
U	(Note 1)
V	18-pin 3/8" x 15/16" dual-in-line
W	22-pin 3/8" x 1-1/8" dual-in-line
X	(Note 1)
Y	(Note 1)
Z	(Note 1)
2	20-terminal 0.350" x 0.350" chip carrier
3	28-terminal 0.450" x 0.450" chip carrier

Note 1: These letters are assigned to packages by individual detail specifications and may be assigned to different packages in different specifications.

TABLE III. 100% Screening Requirements

Screen	Class S		Class B	
	Method	Reqmt	Method	Reqmt
1. Wafer Lot Acceptance	5007	All Lots		—
2. Nondestructive Bond Pull	2023	100%		—
3. Internal Visual (Note 1)	2010, Condition A	100%	2010, Condition B	100%

5. Temp. Cycling (Note 2)	1010, Condition C	100%	1010, Condition C	100%
6. Constant Acceleration	2001, Condition E (Min.) Y ₁ Orientation Only	100%	2001, Condition E, (Min.), Y ₁ Orientation Only	100%
7. Visual Inspection (Note 3)		100%		100%
8. Particle Impact Noise Detection (PIND)	2020, Condition A (Note 4)	100%		—
9. Serialization	(Note 5)	100%		—
10. Interim (Pre-Burn-In) Electrical Parameters	Per Applicable Device Specification (Note 13)	100%	Per Applicable Device Specification (Note 6)	—
11. Burn-In Test	1015 240 Hrs. @ 125°C Min. (Cond. F Not Allowed)	100%	1015 160 Hrs. @ 125°C Min.	100%
12. Interim (Post-Burn-In) Electrical Parameters	Per Applicable Device Specification (Note 13)	100%		
13. Reverse Bias Burn-In (Note 7)	1015; Test Condition A, C, 72 Hrs. @ 150°C Min. (Cond. F Not Allowed)	100%		—
15. PDA Calculation	5% Parametric (Note 14), 3% Functional — 25°C	All Lots	5% Parametric (Note 14)	All Lots
16. Final Electrical Test	Per Applicable Device Specification		Per Applicable Device Specification	
a) Static Tests				
1) 25°C (Subgroup 1, Table I, 5005)		100%		100%
2) Max & Min Rated Operating Temp. (Subgroups 2, 3, Table I, 5005)		100%		100%
b) Dynamic Tests & Switching Tests, 25°C (Subgroups 4, 9, Table I, 5005)		100%		100%
c) Functional Test, 25°C (Subgroup 7, Table I, 5005)		100%		100%

TABLE III. 100% Screening Requirements (Continued)

Screen	Class S		Class B	
	Method	Reqmt	Method	Reqmt
17. Seal Fine, Gross	1014	100%, (Note 8)	1014	100%, (Note 9)
18. Radiographic (Note 10)	2012 Two Views	100%		—
19. Qualification or Quality Conformance Inspection Test Sample Selection	(Note 11)	Samp.	(Note 11)	Samp.
20. External Visual (Note 12)	2009	100%		100%

Note 1: Unless otherwise specified, at the manufacturer's option, test samples for Group B, bond strength (Method 5005) may be randomly selected prior to or following internal visual (Method 5004), prior to sealing provided all other specification requirements are satisfied (e.g. bond strength requirements shall apply to each inspection lot, bond failures shall be counted even if the bond would have failed internal visual).

Note 2: For Class B devices, this test may be replaced with thermal shock method 1011, test condition A, minimum.

Note 3: At the manufacturer's option, visual inspection for catastrophic failures may be conducted after each of the thermal/mechanical screens, after the sequence or after seal test. Catastrophic failures are defined as missing leads, broken packages, or lids off.

Note 4: The PIND test may be performed in any sequence after step 6 and prior to step 16. See MIL-M-38510, paragraph 4.6.3.

Note 5: Class S devices shall be serialized prior to interim electrical parameter measurements.

Note 6: When specified, all devices shall be tested for those parameters requiring delta calculations.

Note 7: Reverse bias burn-in is a requirement only when specified in the applicable device specification. The order of performing burn-in and reverse bias burn-in may be inverted.

Note 8: For Class S devices, the seal test may be performed in any sequence between step 16 and step 19, but it shall be performed after all shearing and forming operations on the terminals.

Note 9: For Class B devices, the fine and gross seal tests shall be performed separate or together in any sequence and order between step 6 and step 20 except that they shall be performed after all shearing and forming operations on the terminals. When 100% seal screen cannot be performed after shearing and forming (e.g. flatpacks and chip carriers) the seal screen shall be done 100% prior to these operations and a sample test (LTPD = 5) shall be performed on each inspection lot following these operations. If the sample fails, 100% rescreening shall be required.

Note 10: The radiographic screen may be performed in any sequence after step 19.

Note 11: Samples shall be selected for testing in accordance with the specific device class and lot requirements of Method 5005

Note 12: External Visual shall be performed on the lot any time after step 19 and prior to shipment.

Note 13: Read and Record when past burn-in delta measurements are specified.

Note 14: PDA shall apply to all static, dynamic, functional, and switching measurements at either 25°C or maximum rated operating temperature.

Military Analog Products Available From National Semiconductor

Listed below are the military class B Analog devices available from National Semiconductor. Many of these are also available as Class S product. Additional information including new product plans can be obtained from our sales offices.

Appendix E

Understanding Integrated Circuit Package Power Capabilities

INTRODUCTION

The short and long term reliability of National Semiconductor's interface circuits, like any integrated circuit, is very dependent on its environmental condition. Beyond the mechanical/environmental factors, nothing has a greater influence on this reliability than the electrical and thermal stress seen by the integrated circuit. Both of these stress issues are specifically addressed on every interface circuit data sheet, under the headings of Absolute Maximum Ratings and Recommended Operating Conditions.

However, through application calls, it has become clear that electrical stress conditions are generally more understood than the thermal stress conditions. Understanding the importance of electrical stress should never be reduced, but clearly, a higher focus and understanding must be placed on thermal stress. Thermal stress and its application to interface circuits from National Semiconductor is the subject of this application note.

FACTORS AFFECTING DEVICE RELIABILITY

Figure 1 shows the well known "bathtub" curve plotting failure rate versus time. Similar to all system hardware (mechanical or electrical) the reliability of interface integrated circuits conforms to this curve. The key issues associated with this curve are infant mortality, failure rate, and useful life.

TL/H/9312-1

FIGURE 1. Failure Rate vs Time

Infant mortality, the high failure rate from time t_0 to t_1 (early life), is greatly influenced by system stress conditions other than temperature, and can vary widely from one application to another. The main stress factors that contribute to infant mortality are electrical transients and noise, mechanical maltreatment and excessive temperatures. Most of these failures are discovered in device test, burn-in, card assembly and handling, and initial system test and operation. Although important, much literature is available on the subject of infant mortality in integrated circuits and is beyond the scope of this application note.

Failure rate is the number of devices that will be expected to fail in a given period of time (such as, per million hours). The mean time between failure (MTBF) is the average time (in hours) that will be expected to elapse after a unit has failed before the next unit failure will occur. These two primary "units of measure" for device reliability are inversely related:

$$\text{MTBF} = \frac{1}{\text{Failure Rate}}$$

Although the "bathtub" curve plots the overall failure rate versus time, the useful failure rate can be defined as the percentage of devices that fail per-unit-time during the flat portion of the curve. This area, called the useful life, extends between t_1 and t_2 or from the end of infant mortality to the onset of wearout. The useful life may be as short as several years but usually extends for decades if adequate design margins are used in the development of a system.

Many factors influence useful life including: pressure, mechanical stress, thermal cycling, and electrical stress. However, die temperature during the device's useful life plays an equally important role in triggering the onset of wearout.

FAILURE RATES vs TIME AND TEMPERATURE

The relationship between integrated circuit failure rates and time and temperature is a well established fact. The occurrence of these failures is a function which can be represented by the Arrhenius Model. Well validated and predominantly used for accelerated life testing of integrated circuits, the Arrhenius Model assumes the degradation of a performance parameter is linear with time and that MTBF is a function of temperature stress. The temperature dependence is an exponential function that defines the probability of occurrence. This results in a formula for expressing the lifetime or MTBF at a given temperature stress in relation to another MTBF at a different temperature. The ratio of these two MTBFs is called the acceleration factor F and is defined by the following equation:

$$F = \frac{X_1}{X_2} = \exp \left[\frac{E}{K} \left(\frac{1}{T_2} - \frac{1}{T_1} \right) \right]$$

Where: X_1 = Failure rate at junction temperature T_1

X_2 = Failure rate at junction temperature T_2

T = Junction temperature in degrees Kelvin

E = Thermal activation energy in electron volts (ev)

K = Boltzman's constant

However, the dramatic acceleration effect of junction temperature (chip temperature) on failure rate is illustrated in a plot of the above equation for three different activation energies in Figure 2. This graph clearly demonstrates the importance of the relationship of junction temperature to device failure rate. For example, using the 0.99 eV line, a 30° rise in junction temperature, say from 130°C to 160°C, results in a 10 to 1 increase in failure rate.

TL/H/9312-2

FIGURE 2. Failure Rate as a Function of Junction Temperature

DEVICE THERMAL CAPABILITIES

There are many factors which affect the thermal capability of an integrated circuit. To understand these we need to understand the predominant paths for heat to transfer out of the integrated circuit package. This is illustrated by Figures 3 and 4.

Figure 3 shows a cross-sectional view of an assembled integrated circuit mounted into a printed circuit board.

Figure 4 is a flow chart showing how the heat generated at the power source, the junctions of the integrated circuit

flows from the chip to the ultimate heat sink, the ambient environment. There are two predominant paths. The first is from the die to the die attach pad to the surrounding package material to the package lead frame to the printed circuit board and then to the ambient. The second path is from the package directly to the ambient air.

Improving the thermal characteristics of any stage in the flow chart of Figure 4 will result in an improvement in device thermal characteristics. However, grouping all these characteristics into one equation determining the overall thermal capability of an integrated circuit/package/environmental condition is possible. The equation that expresses this relationship is:

$$T_J = T_A + P_D (\theta_{JA})$$

Where: T_J = Die junction temperature

T_A = Ambient temperature in the vicinity device

P_D = Total power dissipation (in watts)

θ_{JA} = Thermal resistance junction-to-ambient

θ_{JA} , the thermal resistance from device junction-to-ambient temperature, is measured and specified by the manufacturers of integrated circuits. National Semiconductor utilizes special vehicles and methods to measure and monitor this parameter. All circuit data sheets specify the thermal characteristics and capabilities of the packages available for a given device under specific conditions—these package power ratings directly relate to thermal resistance junction-to-ambient or θ_{JA} .

Although National provides these thermal ratings, it is critical that the end user understand how to use these numbers to improve thermal characteristics in the development of his system using IC components.

TL/H/9312-3

FIGURE 3. Integrated Circuit Soldered into a Printed Circuit Board (Cross-Sectional View)

TL/H/9312-4

FIGURE 4. Thermal Flow (Predominant Paths)

DETERMINING DEVICE OPERATING JUNCTION TEMPERATURE

From the above equation the method of determining actual worst-case device operating junction temperature becomes straightforward. Given a package thermal characteristic, θ_{JA} , worst-case ambient operating temperature, $T_A(\max)$, the only unknown parameter is device power dissipation, P_D . In calculating this parameter, the dissipation of the integrated circuit due to its own supply has to be considered, the dissipation within the package due to the external load must also be added. The power associated with the load in a dynamic (switching) situation must also be considered. For example, the power associated with an inductor or a capacitor in a static versus dynamic (say, 1 MHz) condition is significantly different.

The junction temperature of a device with a total package power of 600 mW at 70°C in a package with a thermal resistance of 63°C/W is 108°C.

$$T_J = 70^\circ\text{C} + (63^\circ\text{C}/\text{W}) \times (0.6\text{W}) = 108^\circ\text{C}$$

The next obvious question is, "how safe is 108°C?"

MAXIMUM ALLOWABLE JUNCTION TEMPERATURES

What is an acceptable maximum operating junction temperature is in itself somewhat of a difficult question to answer. Many companies have established their own standards based on corporate policy. However, the semiconductor industry has developed some defacto standards based on the device package type. These have been well accepted as numbers that relate to reasonable (acceptable) device lifetimes, thus failure rates.

National Semiconductor has adopted these industry-wide standards. For devices fabricated in a molded package, the maximum allowable junction temperature is 150°C. For these devices assembled in ceramic or cavity DIP packages, the maximum allowable junction temperature is 175°C. The numbers are different because of the differences in package types. The thermal strain associated with the die package interface in a cavity package is much less than that exhibited in a molded package where the integrated circuit chip is in direct contact with the package material.

Let us use this new information and our thermal equation to construct a graph which displays the safe thermal (power) operating area for a given package type. Figure 5 is an example of such a graph. The end points of this graph are easily determined. For a 16-pin molded package, the maximum allowable temperature is 150°C; at this point no power dissipation is allowable. The power capability at 25°C is 1.98W as given by the following calculation:

$$P_D @ 25^\circ\text{C} = \frac{T_J(\max) - T_A}{\theta_{JA}} = \frac{150^\circ\text{C} - 25^\circ\text{C}}{63^\circ\text{C}/\text{W}} = 1.98\text{W}$$

The slope of the straight line between these two points is minus the inversion of the thermal resistance. This is referred to as the derating factor.

$$\text{Derating Factor} = -\frac{1}{\theta_{JA}}$$

As mentioned, Figure 5 is a plot of the safe thermal operating area for a device in a 16-pin molded DIP. As long as the intersection of a vertical line defining the maximum ambient temperature (70°C in our previous example) and maximum device package power (600 mW) remains below the maximum package thermal capability line the junction temperature will remain below 150°C—the limit for a molded package. If the intersection of ambient temperature and package power fails on this line, the maximum junction temperature will be 150°C. Any intersection that occurs above this line will result in a junction temperature in excess of 150°C and is not an appropriate operating condition.

TL/H/9312-5

FIGURE 5. Package Power Capability vs Temperature

The thermal capabilities of all integrated circuits are expressed as a power capability at 25°C still air environment with a given derating factor. This simply states, for every degree of ambient temperature rise above 25°C, reduce the package power capability stated by the derating factor which is expressed in mW/°C. For our example—a θ_{JA} of 63°C/W relates to a derating factor of 15.9 mW/°C.

FACTORS INFLUENCING PACKAGE THERMAL RESISTANCE

As discussed earlier, improving any portion of the two primary thermal flow paths will result in an improvement in overall thermal resistance junction-to-ambient. This section discusses those components of thermal resistance that can be influenced by the manufacturer of the integrated circuit. It also discusses those factors in the overall thermal resistance that can be impacted by the end user of the integrated circuit. Understanding these issues will go a long way in understanding chip power capabilities and what can be done to insure the best possible operating conditions and, thus, best overall reliability.

Die Size

Figure 6 shows a graph of our 16-pin DIP thermal resistance as a function of integrated circuit die size. Clearly, as the chip size increases the thermal resistance decreases—this relates directly to having a larger area with which to dissipate a given power.

TL/H/9312-6

FIGURE 6. Thermal Resistance vs Die Size

Lead Frame Material

Figure 7 shows the influence of lead frame material (both die attach and device pins) on thermal resistance. This graph compares our same 16-pin DIP with a copper lead frame, a Kovar lead frame, and finally an Alloy 42 type lead frame—these are lead frame materials commonly used in the industry. Obviously the thermal conductivity of the lead frame material has a significant impact in package power capability. Molded interface circuits from National Semiconductor use the copper lead frame exclusively.

TL/H/9312-7

FIGURE 7. Thermal Resistance vs Lead Frame Material

Board vs Socket Mount

One of the major paths of dissipating energy generated by the integrated circuit is through the device leads. As a result of this, the graph of Figure 8 comes as no surprise. This compares the thermal resistance of our 16-pin package soldered into a printed circuit board (board mount) compared to the same package placed in a socket (socket mount). Adding a socket in the path between the PC board and the device adds another stage in the thermal flow path, thus increasing the overall thermal resistance. The thermal capabilities of National Semiconductor's interface circuits are specified assuming board mount conditions. If the devices are placed in a socket the thermal capabilities should be reduced by approximately 5% to 10%.

TL/H/9312-8

FIGURE 8. Thermal Resistance vs Board or Socket Mount

Air Flow

When a high power situation exists and the ambient temperature cannot be reduced, the next best thing is to provide air flow in the vicinity of the package. The graph of Figure 9 illustrates the impact this has on thermal resistance. This graph plots the relative reduction in thermal resistance normalized to the still air condition for our 16-pin molded DIP. The thermal ratings on National Semiconductor's interface circuits data sheets relate to the still air environment.

TL/H/9312-9

FIGURE 9. Thermal Resistance vs Air Flow

Other Factors

A number of other factors influence thermal resistance. The most important of these is using thermal epoxy in mounting ICs to the PC board and heat sinks. Generally these techniques are required only in the very highest of power applications.

Some confusion exists between the difference in thermal resistance junction-to-ambient (θ_{JA}) and thermal resistance junction-to-case (θ_{JC}). The best measure of actual junction temperature is the junction-to-ambient number since nearly all systems operate in an open air environment. The only situation where thermal resistance junction-to-case is important is when the entire system is immersed in a thermal bath and the environmental temperature is indeed the case temperature. This is only used in extreme cases and is the exception to the rule and, for this reason, is not addressed in this application note.

NATIONAL SEMICONDUCTOR PACKAGE CAPABILITIES

Figures 10 and 11 show composite plots of the thermal characteristics of the most common package types in the National Semiconductor Linear Circuits product family. Figure 10 is a composite of the copper lead frame molded package. Figure 11 is a composite of the ceramic (cavity) DIP using poly die attach. These graphs represent board mount still air thermal capabilities. Another, and final, thermal resistance trend will be noticed in these graphs. As the number of device pins increase in a DIP the thermal resistance decreases. Referring back to the thermal flow chart, this trend should, by now, be obvious.

RATINGS ON INTERFACE CIRCUITS DATA SHEETS

In conclusion, all National Semiconductor Linear Products define power dissipation (thermal) capability. This information can be found in the Absolute Maximum Ratings section of the data sheet. The thermal information shown in this application note represents average data for characterization of the indicated package. Actual thermal resistance can vary from $\pm 10\%$ to $\pm 15\%$ due to fluctuations in assembly quality, die shape, die thickness, distribution of heat sources on the die, etc. The numbers quoted in the linear data

sheets reflect a 15% safety margin from the average numbers found in this application note. Insuring that total package power remains under a specified level will guarantee that the maximum junction temperature will not exceed the package maximum.

The package power ratings are specified as a maximum power at 25°C ambient with an associated derating factor for ambient temperatures above 25°C. It is easy to determine the power capability at an elevated temperature. The power specified at 25°C should be reduced by the derating factor for every degree of ambient temperature above 25°C. For example, in a given product data sheet the following will be found:

Maximum Power Dissipation* at 25°C
 Cavity Package 1509 mW
 Molded Package 1476 mW

* Derate cavity package at 10 mW/°C above 25°C; derate molded package at 11.8 mW/°C above 25°C.

If the molded package is used at a maximum ambient temperature of 70°C, the package power capability is 945 mW.

$$P_D @ 70^\circ\text{C} = 1476 \text{ mW} - (11.8 \text{ mW}/^\circ\text{C}) \times (70^\circ\text{C} - 25^\circ\text{C}) \\ = 945 \text{ mW}$$

APPENDIX F

How to Get the Right Information From a Data Sheet

Not All Data Sheets Are Created Alike, and False Assumptions Could Cost an Engineer Time and Money

By Robert A. Pease

When a new product arrives in the marketplace, it hopefully will have a good, clear data sheet with it.

The data sheet can show the prospective user how to apply the device, what performance specifications are guaranteed and various typical applications and characteristics. If the data-sheet writer has done a good job, the user can decide if the product will be valuable to him, exactly how well it will be of use to him and what precautions to take to avoid problems.

SPECIFICATIONS

The most important area of a data sheet specifies the characteristics that are guaranteed—and the test conditions that apply when the tests are done. Ideally, all specifications that the users will need will be spelled out clearly. If the product is similar to existing products, one can expect the data sheet to have a format similar to other devices.

But, if there are significant changes and improvements that nobody has seen before, then the writer must clarify what is meant by each specification. Definitions of new phrases or characteristics may even have to be added as an appendix.

For example, when fast-settling operational amplifiers were first introduced, some manufacturers defined settling time as the time after slewing before the output finally enters and stays within the error-band; but other manufacturers included the slewing time in their definition. Because both groups made their definitions clear, the user was unlikely to be confused or misled.

However, the reader ought to be on the alert. In a few cases, the data-sheet writer is playing a specsman's game, and is trying to show an inferior (to some users) aspect of a product in a light that makes it look superior (which it may be, to a couple of users).

GUARANTEES

When a data sheet specifies a guaranteed minimum value, what does it mean? An assumption might be made that the manufacturer has actually tested that specification and has great confidence that no part could fail that test and still be shipped. Yet that is not always the case.

For instance, in the early days of op amps (20 years ago), the differential-input impedance might have been guaranteed at $1\text{ M}\Omega$ —but the manufacturer obviously did not measure the impedance. When a customer insisted, "I have to know how you measure this impedance," it had to be explained that the impedance was not measured, but that the base current was. The correlation between I_b and Z_{in} permitted the substitution of this simple dc test for a rather messy, noisy, hard-to-interpret test.

Every year, for the last 20 years, manufacturers have been trying to explain, with varying success, why they do not measure the Z_{in} *per se*, even though they do guarantee it.

In other cases, the manufacturer may specify a test that can be made only on the die as it is probed on the wafer, but cannot be tested after the die is packaged because that signal is not accessible any longer. To avoid frustrating and confusing the customer, some manufacturers are establishing two classes of guaranteed specifications:

- The tested limit represents a test that cannot be doubted, one that is actually performed directly on 100 percent of the devices, 100 percent of the time.
- The design limit covers other tests that may be indirect, implicit or simply guaranteed by the inherent design of the device, and is unlikely to cause a failure rate (on that test), even as high as one part per thousand.

Why was this distinction made? Not just because customers wanted to know which specifications were guaranteed by testing, but because the quality-assurance group insisted that it was essential to separate the tested guarantees from the design limits so that the AQL (assurance-quality level) could be improved from 0.1 percent to down below 100 ppm.

Some data sheets guarantee characteristics that are quite expensive and difficult to test (even harder than noise) such as long-term drift (20 ppm or 50 ppm over 1,000 hours).

The data sheet may not tell the reader if it is measured, tested or estimated. One manufacturer may perform a 100-percent test, while another states, "Guaranteed by sample testing." This is not a very comforting assurance that a part is good, especially in a critical case where only a long-term test can prove if the device did meet the manufacturer's specification. If in doubt, question the manufacturer.

TYPICALS

Next to a guaranteed specification, there is likely to be another in a column labeled "typical".

It might mean that the manufacturer once actually saw one part as good as that. It could indicate that half the parts are better than that specification, and half will be worse. But it is equally likely to mean that, five years ago, half the parts were better and half worse. It could easily signify that a few parts might be slightly better, and a few parts a lot worse; after all, if the noise of an amplifier is extremely close to the theoretical limit, one cannot expect to find anything much better than that, but there will always be a few noisy ones.

If the specification of interest happens to be the bias current (I_b) of an op amp, a user can expect broad variations. For example, if the specification is 200 nA maximum, there might be many parts where I_b is 40 nA on one batch (where the beta is high), and a month later, many parts where the I_b is 140 nA when the beta is low.

Absolute Maximum Ratings (Note 11)

If Military/Aerospace specified devices are required, contact the National Semiconductor Sales Office/Distributors for availability and specifications.

Supply Voltage	+35V to -0.2V
Output Voltage	+6V to -1.0V
Output Current	10 mA
Storage Temperature,	
TO-46 Package	-76°F to +356°F
TO-92 Package	-76°F to +300°F

Lead Temp. (Soldering, 4 seconds) *

TO-46 Package +300°C

TO-92 Package +260°C

Specified Operating Temp. Range (Note 2)

	T _{MIN} to T _{MAX}
LM34, LM34A	-50°F to +300°F
LM34C, LM34CA	-40°F to +230°F
LM34D	+32°F to +212°F

DC Electrical Characteristics (Note 1, Note 6)

Parameter	Conditions	LM34A			LM34CA			Units (Max)
		Typical	Tested Limit (Note 4)	Design Limit (Note 5)	Typical	Tested Limit (Note 4)	Design Limit (Note 5)	
Accuracy (Note 7)	T _A = +77°F	±0.4	±1.0		±0.4	±1.0		°F
	T _A = 0°F	±0.6			±0.6			°F
	T _A = T _{MAX}	±0.8	±2.0		±0.8	±2.0	±2.0	°F
	T _A = T _{MIN}	±0.8	±2.0		±0.8		±3.0	°F
Nonlinearity (Note 8)	T _{MIN} ≤ T _A ≤ T _{MAX}	±0.35		±0.7	±0.30		±0.6	°F
Sensor Gain (Average Slope)	T _{MIN} ≤ T _A ≤ T _{MAX}	+10.0	+9.9, +10.1		+10.0		+9.9, +10.1	mV/°F, min mV/°F, max
Load Regulation (Note 3)	T _A = +77°F T _{MIN} ≤ T _A ≤ T _{MAX} 0 ≤ I _L ≤ 1 mA	±0.4 ±0.5	±1.0	±3.0	±0.4 ±0.5	±1.0	±3.0	mV/mA mV/mA
Line Regulation (Note 3)	T _A = +77°F 5V ≤ V _S ≤ 30V	±0.01 ±0.02	±0.05	±0.1	±0.01 ±0.02	±0.05	±0.1	mV/V mV/V
Quiescent Current (Note 9)	V _S = +5V, +77°F	75	90		75	90		μA
	V _S = +5V	131		160	116		139	μA
	V _S = +30V, +77°F	76	92		76	92		μA
	V _S = +30V	132		163	117		142	μA
Change of Quiescent Current (Note 3)	4V ≤ V _S ≤ 30V, +77°F 5V ≤ V _S ≤ 30V	+0.5 +1.0	2.0	3.0	0.5 1.0	2.0	3.0	μA μA
Temperature Coefficient of Quiescent Current		+0.30		+0.5	+0.30		+0.5	μA/°F
Minimum Temperature for Rated Accuracy	In circuit of Figure 1, I _L = 0	+3.0		+5.0	+3.0		+5.0	°F
Long-Term Stability	T _J = T _{MAX} for 1000 hours	±0.16			±0.16			°F

Note 1: Unless otherwise noted, these specifications apply: -50°F ≤ T_J ≤ +300°F for the LM34 and LM34A; -40°F ≤ T_J ≤ +230°F for the LM34C and LM34CA; and +32°F ≤ T_J ≤ +212°F for the LM34D. V_S = +5 Vdc and I_{LOAD} = 50 μA in the circuit of Figure 2; +6 Vdc for LM34 and LM34A for 230°F ≤ T_J ≤ 300°F. These specifications also apply from +5°F to T_{MAX} in the circuit of Figure 1.

Note 2: Thermal resistance of the TO-46 package is 292°F/W junction to ambient and 43°F/W junction to case. Thermal resistance of the TO-92 package is 324°F/W junction to ambient.

Note 3: Regulation is measured at constant junction temperature using pulse testing with a low duty cycle. Changes in output due to heating effects can be computed by multiplying the internal dissipation by the thermal resistance.

Note 4: Tested limits are guaranteed and 100% tested in production.

Note 5: Design limits are guaranteed (but not 100% production tested) over the indicated temperature and supply voltage ranges. These limits are not used to calculate outgoing quality levels.

Note 6: Specification in **BOLDFACE TYPE** apply over the full rated temperature range.

Note 7: Accuracy is defined as the error between the output voltage and 10 mV/°F times the device's case temperature at specified conditions of voltage, current, and temperature (expressed in °F).

Note 8: Nonlinearity is defined as the deviation of the output-voltage-versus-temperature curve from the best-fit straight line over the device's rated temperature range.

Note 9: Quiescent current is defined in the circuit of Figure 1.

Note 10: Contact factory for availability of LM34CAZ.

** **Note 11:** Absolute Maximum Ratings indicate limits beyond which damage to the device may occur. DC and AC electrical specifications do not apply when operating the device beyond its rated operating conditions (see Note 1).

A Point-By-Point Look

Let's look a little more closely at the data sheet of the National Semiconductor LM34, which happens to be a temperature sensor.

Note 1 lists the nominal test conditions and test circuits in which all the characteristics are defined. Some additional test conditions are listed in the column "Conditions", but Note 1 helps minimize the clutter.

Note 2 gives the thermal impedance, (which may also be shown in a chart or table).

Note 3 warns that an output impedance test, if done with a long pulse, could cause significant self-heating and thus, error.

Note 6 is intended to show which specs apply at all rated temperatures.

Note 7 is the definition of the "Accuracy" spec, and Note 8 the definition for non-linearity. Note 9 states in what test circuit the quiescent current is defined. Note 10 indicates that one model of the family may not be available at the time of printing (but happens to be available now), and Note 11 is the definition of Absolute Max Ratings.

* Note—the "4 seconds" soldering time is a new standard for plastic packages.

** Note—the wording of Note 11 has been revised—this is the best wording we can devise, and we will use it on all future datasheets.

APPLICATIONS

Another important part of the data sheet is the applications section. It indicates the novel and conventional ways to use a device. Sometimes these applications are just little ideas to tweak a reader's mind. After looking at a couple of applications, one can invent other ideas that are useful. Some applications may be of no real interest or use.

In other cases, an application circuit may be the complete definition of the system's performance; it can be the test circuit in which the specification limits are defined, tested and guaranteed. But, in all other instances, the performance of a typical application circuit is not guaranteed, it is only typical. In many circumstances, the performance may depend on external components and their precision and matching. Some manufacturers have added a phrase to their data sheets:

"Applications for any circuits contained in this document are for illustration purposes only and the manufacturer makes no representation or warranty that such applications will be suitable for the use indicated without further testing or modification."

In the future, manufacturers may find it necessary to add disclaimers of this kind to avoid disappointing users with circuits that work well, much of the time, but cannot be easily guaranteed.

The applications section is also a good place to look for advice on quirks—potential drawbacks or little details that may not be so little when a user wants to know if a device will actually deliver the expected performance.

For example, if a buffer can drive heavy loads and can handle fast signals cleanly (at no load), the maker isn't doing anybody any favors if there is no mention that the distortion goes sky-high if the rated load is applied.

Another example is the application hint for the LF156 family:

"Exceeding the negative common-mode limit on either input will cause a reversal of the phase to output and force the amplifier output to the corresponding high or low state. Exceeding the negative common-mode limit on both inputs will force the amplifier output to a high state. In neither case does a latch occur, since raising the input back within the common-mode range again puts the input stage and, thus the amplifier, in a normal operating mode."

That's the kind of information a manufacturer should really give to a data-sheet reader because no one could ever guess it.

Sometimes, a writer slips a quirk into a characteristic curve, but it's wiser to draw attention to it with a line of text. This is because it's better to make the user sad before one gets started, rather than when one goes into production. Conversely, if a user is going to spend more than 10 minutes using a new product, one ought to spend a full five minutes reading the entire data sheet.

FINE PRINT

What other fine print can be found on a data sheet? Sometimes the front page may be marked "advance" or "preliminary." Then on the back page, the fine print may say something such as:

"This data sheet contains preliminary limits and design specifications. Supplemental information will be published at a later date. The manufacturer reserves the right to make changes in the products contained in this document in order to improve design or performance and to supply the best possible products. We also assume no responsibility for the use of any circuits described herein, convey no license under any patent or other right and make no representation that the circuits are free from patent infringement."

In fact, after a device is released to the marketplace in a preliminary status, the engineers love to make small improvements and upgrades in specifications and characteristics, and hate to degrade a specification from its first published value—but occasionally that is necessary.

Another item in the fine print is the manufacturer's telephone number. Usually it is best to refer questions to the local sales representative or field-applications engineer, because they may know the answer or they may be best able to put a questioner in touch with the right person at the factory.

Occasionally, the factory's applications engineers have all the information. Other times, they have to bring in product engineers, test engineers or marketing people. And sometimes the answer can't be generated quickly—data have to be gathered, opinions solidified or policies formulated before the manufacturer can answer the question. Still, the telephone number is the key to getting the factory to help.

ORIGINS OF DATA SHEETS

Of course, historically, most data sheets for a class of products have been closely modeled on the data sheet of the forerunner of that class. The first data sheet was copied to make new versions.

That's the way it happened with the UA709 (the first monolithic op amp) and all its copies, as well as many other similar families of circuits.

Even today, an attempt is made to build on the good things learned from the past and add a few improvements when necessary. But, it's important to have real improvements, not just change for the sake of change.

So, while it's not easy to get the format and everything in it exactly right to please everybody, new data sheets are continually surfacing with new features, applications ideas, specifications and aids for the user. And, if the users complain loudly enough about misleading or inadequate data sheets, they can help lead the way to change data sheets. That's how many of today's improvements came about—through customer demand.

Who writes data sheets? In some cases, a marketing person does the actual writing and engineers do the checking. In other companies, the engineer writes, while marketing people and other engineers check. Sometimes, a committee seems to be doing the writing. None of these ways is necessarily wrong.

For example, one approach might be: The original designer of the product writes the data sheet (inside his head) at the same time the product is designed. The concept here is, if one can't find the proper ingredients for a data sheet—good applications, convenient features for the user and nicely tested specifications as the part is being designed—then maybe it's not a very good product until all those ingredients are completed. Thus, the collection of raw materials for a good data sheet is an integral part of the design of a product. The actual assembly of these materials is an art which can take place later.

WHEN TO WRITE DATA SHEETS

A new product becomes available. The applications engineers start evaluating their application circuits and the test engineers examine their production test equipment.

But how can the users evaluate the new device? They have to have a data sheet—which is still in the process of being written. Every week, as the data sheet writer tries to polish and refine the incipient data sheet, other engineers are reporting, "These spec limits and conditions have to be revised," and, "Those application circuits don't work like we thought they would; we'll have one running in a couple of days." The marketing people insist that the data sheet must be finalized and frozen right away so that they can start printing copies to go out with evaluation samples.

These trying conditions may explain why data sheets always seem to have been thrown together under panic conditions and why they have so many rough spots. Users should be aware of the conflicting requirements: Getting a data sheet "as completely as possible" and "as accurately as possible" is compromised if one wants to get the data sheet "as quickly as possible."

The reader should always question the manufacturer. What are the alternatives? By not asking the right question, a misunderstanding could arise; getting angry with the manufacturer is not to anyone's advantage.

Robert Pease has been staff scientist at National Semiconductor Corp., Santa Clara, Calif., for eleven years. He has designed numerous op amps, data converters, voltage regulators and analog-circuit functions.

Appendix G

Obsolete Product Replacement Guide

Some device types, individual temperature grades and package options have been discontinued. This guide is provided to help design engineers select and specify an appropriate alternative.

NSC Part Number	Replacement	Note	NSC Part Number	Replacement	Note
ADB1200	ADC3711	2	LM1821S	LM1823	2
DAC1200/1201	DAC1265	2	LM1822	LM1823	3

Note 1: IMPROVED REPLACEMENT: Pin for Pin replacement with superior electrical specifications.

Note 2: FUNCTIONAL REPLACEMENT: Consult datasheet to determine suitability of the replacement for specific application.

Note 3: SIMILAR DEVICE with superior performance: Consult datasheet to determine suitability of the replacement for specific application.

Appendix H

Products Not Recommended for New Designs

The popular National Semiconductor Corporation monolithic IC's may have been designed into your systems. We believe that there are more cost-effective circuits manufactured by National Semiconductor Corporation that should be considered in your new designs. These recommendations are listed in this section. To eliminate the necessity to redesign proven equipment, we are continuing to make these products for use in existing designs for which they were uniquely suitable.

NSC Part Number	Recommended Replacement	Note
LH2210	LM210	2
LH2301A	LM301A	2
LH2308A	LM308A	2
LH2310	LM310	2

Bookshelf of Technical Support Information

National Semiconductor Corporation recognizes the need to keep you informed about the availability of current technical literature.

This bookshelf is a compilation of books that are currently available. The listing that follows shows the publication year and section contents for each book.

Please contact your local National sales office for possible complimentary copies. A listing of sales offices follows this bookshelf.

We are interested in your comments on our technical literature and your suggestions for improvement.

Please send them to:

Technical Communications Dept. M/S 23-200
2900 Semiconductor Drive
P.O. Box 58090
Santa Clara, CA 95052-8090

For a recorded update of this listing plus ordering information for these books from National's Literature Distribution operation, please call (408) 749-7378.

ALS/AS LOGIC DATABOOK—1987

Introduction to Bipolar Logic • Advanced Low Power Schottky • Advanced Schottky

ASIC DESIGN MANUAL/GATE ARRAYS & STANDARD CELLS—1987

SSI/MSI Functions • Peripheral Functions • LSI/VLSI Functions • Design Guidelines • Packaging

DATA CONVERSION/ACQUISITION DATABOOK—1984

Selection Guides • Active Filters • Amplifiers • Analog Switches • Analog-to-Digital Converters
Analog-to-Digital Display (DVM) • Digital-to-Analog Converters • Sample and Hold • Sensors/Transducers
Successive Approximation Registers/Comparators • Voltage References

HYBRID PRODUCTS DATABOOK—1982

Operational Amplifiers • Buffers • Instrumentation Amplifiers • Sample & Hold Amplifiers • Comparators
Non-Linear Functions • Precision Voltage Regulators and References • Analog Switches
MOS Clock Drivers • Digital Drivers • A-D Converters • D-A Converters • Fiber-Optic Products
Active Filters & Telecommunication Products • Precision Networks • 883/RETS

INTERFACE DATABOOK—1986

Transmission Line Drivers/Receivers • Bus Transceivers • Peripheral/Power Drivers • Display Controllers/Drivers
Memory Support • Microprocessor Support • Level Translators/Buffers • Frequency Synthesis

INTERFACE/BIPOLAR LSI/BIPOLAR MEMORY/PROGRAMMABLE LOGIC DATABOOK—1983

Transmission Line Drivers/Receivers • Bus Transceivers • Peripheral/Power Drivers
Level Translators/Buffers • Display Controllers/Drivers • Memory Support • Dynamic Memory Support
Microprocessor Support • Data Communications Support • Disk Support • Frequency Synthesis
Interface Appendices • Bipolar PROMs • Bipolar and ECL RAMs • 2900 Family/Bipolar Microprocessor
Programmable Logic

INTUITIVE IC CMOS EVOLUTION—1984

Thomas M. Frederiksen's new book targets some of the most significant transitions in semiconductor technology since the change from germanium to silicon. *Intuitive IC CMOS Evolution* highlights the transition in the reduction in defect densities and the development of new circuit topologies. The author's latest book is a vital aid to engineers, and industry observers who need to stay abreast of the semiconductor industry.

INTUITIVE IC OP AMPS—1984

Thomas M. Frederiksen's new book, *Intuitive IC Op Amps*, explores the many uses and applications of different IC op amps. Frederiksen's detailed book differs from others in the way he focuses on the intuitive groundwork in the basic functioning concepts of the op amp. Mr. Frederiksen's latest book is a vital aid to engineers, designers, and industry observers who need to stay abreast of the computer industry.

LINEAR APPLICATIONS HANDBOOK—1986

The purpose of this handbook is to provide a fully indexed and cross-referenced collection of linear integrated circuit applications using both monolithic and hybrid circuits from National Semiconductor.

Individual application notes are normally written to explain the operation and use of one particular device or to detail various methods of accomplishing a given function. The organization of this handbook takes advantage of this innate coherence by keeping each application note intact, arranging them in numerical order, and providing a detailed Subject Index.

LINEAR 2 DATABOOK—1988

Active Filters • Analog Switches/Multiplexers • Analog-to-Digital • Digital-to-Analog • Sample and Hold
Sensors • Voltage References • Surface Mount

LINEAR 3 DATABOOK—1988

Audio Circuits • Radio Circuits • Video Circuits • Motion Control • Special Functions • Surface Mount

LINEAR SUPPLEMENT DATABOOK—1984

Amplifiers • Comparators • Voltage Regulators • Voltage References • Converters • Analog Switches
Sample and Hold • Sensors • Filters • Building Blocks • Motor Controllers • Consumer Circuits
Telecommunications Circuits • Speech • Special Analog Functions

LOGIC DATABOOK VOLUME I—1984

CMOS AC Switching Test Circuits and Timing Waveforms • CMOS Application Notes • MM54HC/MM74HC
MM54HCT/MM74HCT • CD4XXX • MM54CXXX/MM74CXXX • LSI/VLSI

LS/S/TTL DATABOOK—1987

Introduction to Bipolar Logic • Low Power Schottky • Schottky • TTL • Low Power

MASS STORAGE HANDBOOK—1986

Disk Interface Design Guide and User Manual • Winchester Disk Support • Winchester Disk Data Controller
Floppy Disk Support • Drive Interface Support Circuits

MEMORY SUPPORT HANDBOOK—1986

Dynamic Memory Control • Error Checking and Correction • Microprocessor Interface and Applications
Memory Drivers and Support

MICROCOMMUNICATION ELEMENTS DATABOOK—1987

CPU • Peripherals • Evaluation Board • Logic Devices

NON-VOLATILE MEMORY DATABOOK—1987

CMOS EPROMs • EEPROMs • Bipolar PROMs

SERIES 32000 DATABOOK—1986

Introduction • CPU-Central Processing Unit • Slave Processors • Peripherals • Data Communications and LAN's
Disk Control and Interface • DRAM Interface • Development Tools • Software Support • Application Notes

RANDOM ACCESS MEMORY DATABOOK—1987

Static RAMs • TTL RAMs • TTL FIFOs • ECL RAMs

RELIABILITY HANDBOOK—1986

Reliability and the Die • Internal Construction • Finished Package • MIL-STD-883 • MIL-M-38510
The Specification Development Process • Reliability and the Hybrid Device • VLSI/VHSIC Devices
Radiation Environment • Electrostatic Discharge • Discrete Device • Standardization
Quality Assurance and Reliability Engineering • Reliability and Documentation • Commercial Grade Device
European Reliability Programs • Reliability and the Cost of Semiconductor Ownership
Reliability Testing at National Semiconductor • The Total Military/Aerospace Standardization Program
883B/RETSTM Products • MILS/RETSTM Products • 883/RETSTM Hybrids • MIL-M-38510 Class B Products
Radiation Hardened Technology • Wafer Fabrication • Semiconductor Assembly and Packaging
Semiconductor Packages • Glossary of Terms • Key Government Agencies • AN/ Numbers and Acronyms
Bibliography • MIL-M-38510 and DESC Drawing Cross Listing

TELECOMMUNICATIONS—1987

Line Card Components • Integrated Services Digital Network Components • Modems
Analog Telephone Components • Application Notes

THE SWITCHED-CAPACITOR FILTER HANDBOOK—1985

Introduction to Filters • National's Switched-Capacitor Filters • Designing with Switched-Capacitor Filters
Application Circuits • Filter Design Program • Nomographs and Tables

TRANSISTOR DATABOOK—1982

NPN Transistors • PNP Transistors • Junction Field Effect Transistors • Selection Guides • Pro Electron Series
Consumer Series • NA/NB/NR Series • Process Characteristics Double-Diffused Epitaxial Transistors
Process Characteristics Power Transistors • Process Characteristics JFETs • JFET Applications Notes

VOLTAGE REGULATOR HANDBOOK—1982

Product Selection Procedures • Heat Flow & Thermal Resistance • Selection of Commercial Heat Sink
Custom Heat Sink Design • Applications Circuits and Descriptive Information • Power Supply Design
Data Sheets

48-SERIES MICROPROCESSOR HANDBOOK—1980

The 48-Series Microcomputers • The 48-Series Single-Chip System • The 48-Series Instruction Set
Expanding the 48-Series Microcomputers • Applications for the 48-Series • Development Support
Analog I/O Components • Communications Components • Digital I/O Components • Memory Components
